4110. But at night, each seeing both lights of the other, they would port their helm and go across the other's bows, if they complied with the law; is not that the case?—Yes, if each of them have the rays of both lights open; if they see the three lights ahead, or a little on the bow, certainly they would.

4111. Do you see any necessity for their taking that action; if the lights were more finely screened they would not do it perhaps. Do you think that ships at sea now cross each other's bows sometimes unnecessarily, to act according to the law?—No, I do not think that.

4112. (*Chairman.*) What is put to you is this. If you screen to 4°, vessels when they are half a point, say, off each other's course would each of them see, presumably from perfectly opposite courses, both lights; under those circumstances it would be the duty of each of them to port, and each of them in those circumstances would cross the bow of the other?—Yes.

4113. Whereas if they kept their course they would pass clear of one another?—Yes, that is right.

4114. What the Admiral was putting to you, I think, was, whether you saw any necessity under those circumstances for their crossing the bows of each other, or whether it would be better that they should be allowed to pass starboard to starboard?—Certainly it would be better that they should not cross each other's bows.

4115. (*Rear-Admiral Andoe.*) That is what I was driving at; it would appear that owing to coarse screening ships sometimes cross each other's bows unnecessarily, because they are bound to do it by the law; whereas with finer screening they would not open each other's two lights?—I quite see what you mean.

4116. Is that right?—That is quite right.

4117. (*Captain Hallett.*) When you made those experiments, what particular wicks had you, do you remember?—Our wicks were 2¼ inches.

4118. Single wicks?—No, three wicks, triangular, laying at a diameter of 2¼ inches.

4119. So that whichever way you looked at the lamp you had the full diameter of the flame?—Yes.

4120. Have you ever tried the electric light?—No.

4121. (*Mr. Bolam.*) You say 2¼ inches; that is nearly 4° across the bow from the outside of the wick.

4122. (*Captain Hallett.*) I think you said it would take up about one-third of the present screening?—Yes, that is about it.

4123. That would be to take off a degree and a half, roughly; that would leave you about 2½°; that is about what you would get. If you take a third of 4°,

*Capt. W. Chapman.*

26 June 1895.

it is very nearly 1½°; that would leave you 2½° across the bow by your screening right ahead on the inner edge of your triangular wick?—Yes; that of course would slightly vary with the width of the wick.

4124. Are all your company's lamps made with wicks in that way?—No. Many of them are duplex lamps only, with two wicks, one alongside the other; but these are Harvie's last new lamps; they are very large lamps, with three wicks in a triangle.

4125. Those are wicks we have not seen at all.

4126. (*Rear-Admiral Andoe.*) Do you consider they are better than the others?—Yes; they are magnificent lamps. On a hazy night you see the glare in the lamp, without seeing the wick at all, at pretty nearly a third of a mile; you clearly see the red and green light without seeing the wick—with the wick shut out.

4127. (*Captain Hallett.*) Was that the only lamp you experimented with?—I tried it with the other ships, with the two wicks, but not for distance. I did not measure the distance. I did it more roughly.

4128. Then you cannot speak to experiments made with the wicks that you have got practically in use?—Yes, these are in use.

4129. They are in use?—Yes.

4130. Generally in your ships?—In the last two ships.

4131. They are gradually coming in, but they are not generally in use yet?—No. I think that is probably a question of the size of the lamps; these are very large lamps.

4132. But what I am driving at is, that the majority of ships do not carry as good lamps as that?—No; but my experiment with that was rather against my opinion that the lamps should be screened right ahead from the inside of the wick; because if I were to get one of the other lamps it would cut it off at a smaller angle; that is the worst position.

4133. (*Mr. Bolam.*) The Board of Trade are afraid of this. They hold that there is a very valuable rhyme: "Green to green, red to red, perfect safety, go ahead;" and they say, if the lights are screened to less than 4° from the outside, that rule will not be a safe one. Now, do you think that is a safe rule at sea at all; that if any officer sees the green to green he is bound to assume that there is perfect safety without any limitation, except that there is green to green?—If you do not show the lights too much across the bow, yes.

4134. You think that is the danger?—No. I think it is safe. The more you throw the lights across the bow the less chance of safety there is.

4135. Then, in point of fact, your argument would be this: Assuming the Board of Trade case is to conserve this rule, green to green, you would say the best way to conserve that rule is to make the angle of screening as small as possible?—If the light could be thrown so that it only showed right ahead, then you would be perfectly safe with green to green, because nobody would be so foolish as to deliberately let a green light run inside his green light, or hit against his glass.

4136. The case as laid down by the Board of Trade is this. If you have two vessels of 60 feet beam 4° on each other's starboard bow, that is to say, practically with a red light just hid, and they steer on parallel courses, they will pass clear by 120 feet, that is, two beams; while if they are screened to 2° from the outside, under the same conditions they will only pass by 14¼ feet. Now, in point of fact, as regards navigation at sea and the safety of life and property, which you have to deal with in your service, is there any substantial difference between the ships passing by two beams and passing by 14·38 feet. I mean, do you navigate to a few feet like that?—I think it is straining at gnats; you cannot keep the ships on a railway line like that.

4137. Then, in point of fact, you think the 4° angle would be of no more value than the 2° angle in conserving that rhyme, "Green to green, red to red, "perfect safety, go ahead"?—No, I think it would be better to get the line as much cut off as much ahead as you can.

4138. Then is green to green and red to red perfect safety in any case whatever; that is to say, is it universally true? The rhyme tells us it is universally true; is it?—I have never seen the object or use of the rhyme myself; but there is no doubt but what, under any ordinary management and with proper care, green to green ought to be safe.

4139. But, after all, what an officer looks to is not the colour of the light but the change of bearing?—Well, colour of light and change of bearing combined. But to bring the ships into the position you are mentioning they must remain on the same bearing continuously, and both green lights must be first seen exactly right ahead, or almost exactly right ahead, because the small angle in a distance such as that would not be appreciable.

4140. In fact, Mr. Gray's rhyme wants a line introduced: "Green to green, red to red (with a pretty "smart change of bearing), perfect safety, go ahead;" or something of that sort?—I really do not know that you want a rhyme at all. What I mean is they are not going to knock their side-lights against each other. I am not certain that the rhyme was intended to be applied in that literal and precise manner.

4141. (*Rear-Admiral Andoe.*) "Perfect safety" is a dangerous expression?—No doubt.

4142. (*Mr. Bolam.*) In the case of the Board of Trade, it is thought that Mr. Gray believed that the screening was exceedingly broad, fully 4° or more, and that in consequence of that he made this rhyme; and if the screening were reduced it would destroy the value of this rhyme, and that would be a calamity to the sea service. I think that is the way it is put. In point of fact, you think the rhyme itself, as it stands, is not a very important matter to be maintained?—No, I do not think there is anything in it.

4143. (*Mr. Scrutton.*) Can you give me the size of the lamps in which you have these wicks of 2½ inches; the ordinary lamp is 9 by 9? Do you happen to know what the sizes are?—I really could not say exactly.

4144. Could you send them to us?—Yes, I can send it; not till one of the ships comes in, but I could then.*

4145. But you feel quite sure that 2½ inches is the size?—Oh, yes, that was measured. I have had drawings made of it.

4146. Then what is the size of the duplex; do you happen to know that; what is the length of the duplex?—Nearly 2 inches, I think; close upon 2 inches.

4147. Would you mind verifying that and letting us have a note of it?—Yes.

4148. Do you mean Harvie's lamps?—Harvie's lamps.

(*Captain Hallett.*) Mr. Harvie has spoken here of 1-inch duplex lamps.

4149–50. (*Mr. Scrutton.*) I simply draw attention to this because that is beyond what we have had before, although we have had Mr. Harvie before us. However, you will kindly let us have the particulars?—I will have them measured and send you the information.

4151. Then I understand you to say that vessels screened to the same angle may meet each other, one showing only the one light, and the other showing the two?—If the courses are slightly different, within half a point of each other.

4152. Would it be possible for you, without inconvenience, to let us have a small sketch in which you would show that, because it is important?—Very well, I will send it you. I do not mean to say that they will remain long in that position, but where the danger comes in is, say, from Gibraltar to Ushant, where the ships are running generally nearly on opposite courses. In thick weather you see a masthead-light, perhaps, a mile off, or three-quarters of a mile off, and you suddenly see the other steamer's lights at close quarters, within half a mile.

4153. One vessel will see two lights and the other vessel will only see one light?—Yes; and the distance between the angles of the rays clearing the vessel will not be large, but it will be sufficient to make one man starboard and the other man port, or conversely.

4154. (*Mr. Bolam.*) Will you in your diagram kindly show us how that it is affected by the screening, if affected at all. It seems to me this is just that unfortunate case which no one can ever get over by any

* Captain Chapman subsequently wrote that the wicks measured 1¼ to 2 inches across, the flame measuring 2½ inches. The lamp in which this burner is used is 7.6 inches in diameter, 9½ inches high, and with the chimney, 20½ inches high; it is carried in a lighthouse slung on gimbals. This burner is used in nine vessels of the Royal Mail Company's fleet. The other vessels have ordinary duplex burners.

screening at all—that it will only be got over by the intelligence of the officer?—It can be got over by throwing the crossing angle further ahead of each ship; because the limit within which the other ship can be within the ray of the three lights is considerably reduced, and the ships are farthest from each other at the time when it is possible for this to happen. It may vary from three-quarters of a mile in one instance to a mile and a quarter in another, and if they each put their helms over a little it will be all right; they will not then be close to each other.

4155. Of course if that was done in time, there is time to rectify any mistake if one is made?—Not with a ship going at any speed. If you once put the helm over it must stop that way when you are close like that.

4156. (*Sir E. Harland.*) You referred to this magnificent lamp with the three wicks. May I ask if each wick is adjusted by a separate screw?—I think so, but I will not be certain—I am nearly certain they were.

4157. You will see the point is rather a difficult one, namely, how the three screws can be brought all to act from the inner side of the lantern?—Well, I did not notice that.

4158. Excuse my putting so detailed a question to you, but we are giving some consideration to the construction of lamps, as it appears from our evidence that lamps vary so much in the quality of their light, due in all probability to the various methods of arranging the wicks, and this appears to us quite new. Would you say that this is a better light than the duplex lamp?—I think I have said so already. Each wick is not 2½ inches, you know.

4159. Then we all misunderstood you?—I do not know what the thickness of the wick is, but the diameter of the circle formed by the three wicks is 2¼ inches. That would be approximately the same as one wick at a distance.

4160. No, that would be much less than 2¼ inches; probably that would be more like 1½ inches. However we can easily find that out?—I said it was a triangular wick with a diameter of 2¼ inches. The wicks are not absolutely close together; the angles do not join entirely; there is a little space.

4161. (*Mr. Bolam.*) It comes to this; if it is a circle 2¼ inches in diameter you will practically have 2¼ inches of light almost each time.

4162. (*Captain Hallett.*) Have you those lamps now at Southampton?—No, the ships are away. I shall have one of the ships home in a fortnight.

4163. (*Sir E Harland.*) I make out that it would not produce more than 1½ inch wick; that is very likely what it would be. Would you have your spare lamps exactly the same?—Yes.

4164. So that they would be interchangeable?—Both sets alike, yes.

4165. I put the question to ascertain whether, if it were not so, it would not make a difference to the screen. If you had to fix a larger lantern into the same case, with the same screen, is it not probable that the screen which suited one size lantern would be wrong for the other size lantern?—Yes, it would, but the lamps are the same size and the screen is measured to each lamp.

4166. But is the lantern the same in each case?—Yes, for both lamps.

4167. That is to say, this arrangement of a triangular wick does not necessitate a larger lantern?—Yes, the lanterns are larger than we have in the other ships, but the spare lanterns are the same size.

4168. And in those spare lanterns what is the arrangement of the wick?—The same.

4169. Am I to gather from that that this arrangement of wicks really necessitates a larger lantern; that is the point?—No, I fancy the lantern is larger merely because the ship is larger.

4170. Then the ship being larger you prefer to have a more powerful light?—Exactly.

4171. Just as in a small coasting craft, it would be a very small one?—Just so.

4172. I suppose the expense of the extra size has nothing to do with it?—I do not think that is considered.

4173. Are you aware that it is considered in small ships?—I have no doubt it is in small ships.

4174. With reference to the masthead-light, have you any wish to see the side-lights placed abaft the masthead-light, or immediately below the masthead-light on the forecastle, as an indication, or a possible indication, of the course the ship is steering?—No, I would rather have the side-lights placed under the masthead-light.

4175. Underneath?—Well, as nearly underneath as you can get it. It must be a little abaft it, unless you have the masthead-light on the mast generally, because if you have the side-lights abaft the masthead-light you may get it obstructed by the hawsers that are sometimes coiled up, or something of that kind. You will never get it exactly the same distance in all ships.

4176. But supposing it were a rule or recommendation which most, if not all, shipowners, where they possibly could, would elect to follow—supposing you had that, and supposing that these side-lights, as you know they are in large ships, are fixed above the reach of any coils of hawsers—on the deckhouse forward—would you, in that case, advise, or prefer, that they should be abaft the masthead-lights or not?—I do not think it makes much difference. I do not think you can place much dependence on that.

4177. But suppose they were dependent on it?—I do not see that there is anything to be gained by it.

4178. Some of our witnesses have set forth that if such were the general rule they would be able to at once form a pretty correct idea of the course that a vessel was steering, especially when she was crossing their bow?—Yes, that would be of assistance.

4179. And also in that vessel meeting you, were that angle (an angle of 45° between the masthead-light and the side-lights) getting less and less, so would the vessel be approaching you more nearly bow on. This model may perhaps serve to indicate what I mean. If the side-lights were at an angle of 45° abaft the masthead-light, the vessel crossing your path would be steering from *that* angle; whereas if the vessel were approaching you more nearly, *that* angle would then become less. Would such an indication in navigation be of any value?—Well, it would, but you would have trouble to get it always at that exact angle in the ship.

4180. I suppose you are referring to the various positions of masthead-lights, and the various deckhouse arrangements, or the absence of them, enabling you to put your side-lights abaft the masthead-lights?—Yes. In small ships you might get them at that angle, but in a large ship you would have a difficulty, I think, unless you carried the masthead-light very high indeed.

4181. In large ocean steamers with long ranges of deckhouses, would it not be more easily arranged? Does it occur to you that the captain's bridge is generally something like that distance abaft the foremast, where the masthead-light is?—Yes; but I do not like lights on the bridge.

4182. Then where would you have the light?—I would rather have them forward. If you have them on the bridge, on a hazy night the green light completely blinds you.

4183. Is there no closed in bulwark at the end of the captain's bridge; are there not rails across there, or something?—That does not matter; the rays of the green light come right across in front of you.

4184. Then the view you take is that it is better to have them on the forecastle deck than on the captain's bridge?—Yes.

4185. How would you carry those lights; you would find it necessary to have them in a lighthouse?—Certainly.

4186. Do you think they would be safely carried in the heaviest weather in a lighthouse?—Yes.

4187. Entered from the deck below?—Yes.

4188. What about vessels in the North Atlantic trade, where all that might be ice bound?—I do not think that would happen. Our lights are always carried now, in the newest ships, in lighthouses. The men can get in in the roughest weather to trim them.

4189. But do your vessels ever experience on their voyages the same intense frost as in the North Atlantic trade?—No.

*Capt. W. Chapman.*

26 June 1895.

4190. In the North Atlantic service, would it be possible to avoid those lights being utterly blinded by ice?—You mean the difference caused by the heat of the lamps.

4191. No, I am referring to the vessel ploughing into the sea?—I do not think so, because of the spray; if the ship is diving into it, the lights on the bridge would be covered with spray, which would freeze just as hard there as anywhere else.

4192. You said that you prefer to have side-lights immediately below the masthead lights; what was your object in that?—Only to keep the lights forward. I should prefer the lights to be as far forward of the bridge as they can safely be.

4193. You object to their being at the edge of the captain's bridge abaft the foremast?—Yes, on account of the rays they throw across.

4194. You would prefer them to be below the masthead lights, but the best place, you think, is on the forecastle?—On the forecastle, yes.

4195. (*Rear-Admiral Andoe.*) May I ask one further question. As a seaman, do you think it would be desirable for the position of the side-lights to be fixed with reference to the masthead-light, as nearly as may be, in all ships?—No.

4196. Do you think it would be of assistance to seamen in passing one another to determine the position of each other?—Yes, I think it would; but I think you are going to have great difficulty with that with regard to different sized ships.

4197. I am putting aside construction. I am speaking now of the point of view of the seaman. As the captain of a ship at sea, do you think it would facilitate observation?—Oh, it would be better to have them all the same.

4198. Because at the present time sometimes you see the bow-lights before the masthead-lights; sometimes abaft the masthead-light, sometimes immediately below the masthead-light; consequently you are not at all sure how the ship is going?—Just so.

4199. Therefore, do you think that if and so far as it were practicable, it would be desirable, to have the lights always in the same position relatively to the masthead-light?—Yes, it would be, decidedly.

4200. I mean from a seaman's point of view?—Decidedly, it would.

*Mr. T. J. Richards.*

Mr. THOMAS J. RICHARDS called and examined.

4200*a*. (*Chairman.*) I believe you are a surveyor in the service of the Board of Trade, and have been so for over 23 years?—Yes.

4201. In the course of your duties have you inspected a large number of ship's lights?—Yes.

4202. What has been your practice with regard to screening ship's lights?—To have the depth of the chock equal to the distance between the screen and the inner edge of the lens.

4203. Before 1892?—Yes, that was always the case.

4204. How did you say you screened lights before the new rule came into force?—So that, assuming the screens are parallel, the depth of the chock should be equal to the distance from the inner edge of the lens to the side of the screen.

4205. So that in other words you screened to the inner edge of the lens?—Yes, that was so formerly.

4206. Can you tell me whether that was the same thing as screening to the inner edge of the wick, and if not how much difference there would be? Was the inner edge of the lens about the same thing as the inner edge of the wick or not?—No, I should not think so.

4207. What was the sort of difference, do you think?—It would be about an inch, I should think, or thereabouts. I cannot say that I remember measuring that specially.

4208. As compared with the present angle of 4° from the outside edge of the wick, what angle would that give?—When the new regulations regarding the 4° angle came in I found that it made little or no difference.

4209. Then is it your view, with regard to the vessels that you examined and approved before the new rules came into operation, that the screening was substantially the same?—Yes.

4210. Where have you inspected lights—in what part of England?—I was for some years in the Tyne district also at Cardiff, and at other ports. Latterly, I have been in London.

4211. How long, may I ask, have you been in London?—About two years and a half.

4212. Before 1892, I mean. What I really wanted to know was this. Were you ever at the same ports before and after the regulation of 1892?—This rule came into force when I was at Cardiff.

4213. So that you saw the old state of things and the new state of things at Cardiff?—Yes, at Cardiff, and I then observed to the authorities in London that in my experience it made little or no difference. The lights were practically screened to the 4° angle as we had been screening them.

4214. I see you say you have passed other equivalent plans—that is plans equivalent to having a chock equal in thickness to the difference between the inner edge of the lens and the outside of the screen—to obtain the same object. What plans are those?—Supposing I found that the screens were bent outwards so as to have the effect of putting the chock on the parallel screen, I should accept that.

4215. So that, however it was got at, what you really did was always to see that the screen was to the edge of the lens somehow or other?—Yes, that is so, ever since I have been in the Board of Trade.

4216. And you reported to the authorities that it made very little alteration in the screening obeying the new as compared with obeying the old regulations?—That is so—that is the case.

4217. You say it made very little alteration. In what direction was even the slight alteration that you noticed?—In my opinion the lights were screened a little more broadly—a little more than 4°.

4218. (*Sir E. Harland.*) They were previously?—Yes, a little more if anything.

4219-20. (*Chairman.*) You think, and no doubt you are quite right in thinking, that it is necessary for the red and green lights to cross slightly, so as to ensure that the lights should be uniform from right ahead to two points abaft the beam. Now as to the angles between 4° and a less angle, what is your opinion? Is it your opinion that 4° is a good angle to screen at?—Yes, I have formed the opinion that the angle is not too great in order to ensure safety; that vessels may go clear of one another.

4221. In your judgment, as I understand it, there is no danger in the lights being screened to 4°?—I think not.

4222. Of course it must be admitted to be the case that if they are screened to 4°, and therefore see both the lights of each other, and obey the rule, of course it follows that they do cross each other's bows?—You mean the lights do?

4223. Each vessel crosses the bows of the other. That must be so?—Quite so, yes.

4224. What I rather want to get from you is this. Do you see any reason why they should cross each other's bows? Suppose they were originally on the starboard side of each other, why should they not remain on the starboard side of each other, why should the vessels cross?—It seems to me that for safety you must have the lights to cross.

4225. I do not know whether you have had any experience at sea?—Yes, I was an engineer at sea.

4226. So you have had some opportunity of judging?—Yes. Of course I am not a seaman; I am an engineer.

4227. However, as you have considered the matter, we may just as well have the benefit of your opinion. What I was putting to you was this. If the lights are screened 4°, they would see each other's two lights when, in point of fact, they were each, we will say, on the starboard side of the other?—Quite so.

4228. If they are each on the starboard side of the other, why should they not remain so?—I see no reason why they should not, if you could get both to act in a safe manner.

4229. Of course. Therefore, assuming that both of them when they were starboard to starboard—I carefully abstain from saying green to green—but when they are starboard to starboard, if both of them see the green light of the other, and they are in fact starboard to starboard, there is no reason, is there, why they should cross each other's bows?—Except that you want both vessels to act in such a way as will keep them in a safe position, and it seems to me that in order to do that, you must have one universal rule that they should port their helms and go clear.

4230. But why should not this be the universal rule. If you screen them so that each sees the green light of the other, why should not they keep on?—They would do that, of course, under those conditions in daylight, but I do not see that they can do that at night, simply because you are bound to have the lights cross so much as will enable the vessels to go clear of one another. Perhaps I do not quite understand your question.

4231. What I was putting to you is this. You have two vessels on parallel and opposite courses, starboard to starboard. If you could so arrange that in that case they should each of them see only the green light of the other, is there any reason why they should not proceed and pass starboard to starboard?—It seems to me you cannot have those conditions in order to enable the vessels to go clear of one another, assuming they each keep their separate courses.

4232. That is a very fine matter, is it not? Of course I quite follow what you point out, but if the vessels are exactly on opposite courses, and running, as one of the witnesses put it, on railway lines, they would or might touch the sides of each other. Is that the consideration that weighs with you in saying that the lights ought not to be screened finer than 4°?—That is the view that I hold; yes.

4233. The answer which seamen give is that under those circumstances the safer and better thing is that each vessel should give a touch of the starboard helm. What do you say to that?—Of course I am not a seaman, but I have thought over the matter and it seems to me there would be a certain amount of danger in that, owing to the uncertainty as to what would be done by both the vessels.

4234. Now; is there any other reason that strikes you why 4° is preferable to a finer angle?—One reason I have for thinking 4° is the proper angle is that by simply altering the course of each vessel a point they go abundantly clear; so that I cannot see why the 4° angle, having other advantages, should not be allowed to remain. Each vessel alters her course a point and they go clear. At about a distance of a mile they can have a distance of, I think, about 800 feet between them.

4235. But if they are screened finer they need not even alter that point?—If you screen them say to 2°, then, assuming each vessel is just out of the line of visibility of both the other vessel's lights, they would be running straight ahead towards one another, and they may come into collision or be in danger of doing so.

4236. That comes to the very same point that I was putting to you just now. Beyond that is there any other reason that strikes you why 4° is preferable to a finer angle?—No; it seems to me the reasons I give are abundantly sufficient for keeping the 4°. I cannot see any reason why it should be altered.

4237. (*Rear-Admiral Andoe.*) Not being a seaman, I presume you have never had charge or control of a ship under way, have you?—No.

4238. Then I suppose the opinions you have expressed regarding the movement of these ships in consequence of their sighting one another's lights are purely theoretical; not the result of your own personal experience at sea?—Not the result of my personal experience at sea; but it seems to me the opinions I have expressed are such as any person can hold, and hold clearly and strongly, simply by laying down the positions of the vessels on a sheet of paper.

4239. Does not the position of the wick in the lamps vary very much in different lamps in ships?—Not very much.

4240. Would you expect to find the wick in all lamps almost precisely in the same position with regard to the screen—the distance from the screen which gives the line parallel to the keel?—I presume you refer to the distance of the wick from the side of the lamp, because the position of the lamp with reference to the screen does vary a very great deal.

*Mr. T. J. Richards.*

26 June 1895.

4241. I know, but I wanted to know with regard to the screen. Would you expect to find the wick with regard to the screen that gives the line parallel to the keel precisely in the same position in all ships?—No; there is a good deal of difference, simply because the position of the lamp with reference to the screen differs a great deal, some lamps are put close, others are put further out.

4242. Then with regard to the lamp itself, do you find the position of the wick nearly always the same distance from the side of the lamp?—Well, not exactly, but there is a considerable similarity in the position.

4243. You could not say that they are always exactly alike?—No; of course you have to deal with the lamps of various makers.

4244. It is from the wick that you get the light, and consequently the angle depends on the position of the wick?—Quite so. You are now speaking of the old lamps.

4245. Yes, before 1892. Now you take the outer edge of the wick?—Yes.

4246. In surveying lamps and screens at ports where you have been, what actual steps did you take to verify the accuracy of the screening?—Do you mean always? I do not know whether you refer to the present state of things.

4247. I mean as a rule what steps did you take to verify the accuracy of the screening?—In the first place I ascertain that the screens are parallel with the centre line of the vessel.

4248. How do you ascertain that?—Stretch a line from the centre line of say the top gallant forecastle to the foremast, and then measure from that centre line to the foreward and after end of each screen.

4249. Is it the practice of the surveyor to do that?—Yes.

4250. Do the smaller cargo vessels carry, in your opinion, lights sufficiently good to make them visible at the regulation distance at sea?—Well, they do not carry such high class lamps as the larger class of vessels, but they carry lamps in accordance with the Board of Trade regulations; that is, with burners not less than one inch broad—when paraffin is burnt.

4251. Have you got any means of testing those lamps so as to know whether they show the regulation distance?—No.

4252. That is never done?—We have no means of testing them. Of course we are influenced by the tests which have been carried out from time to time by the Board of Trade, and the instructions which the Board of Trade have issued to us.

4253. But you never by your own actual observation prove that they are up to the specification as far as power goes?—No, I have always understood that with a lamp of the description that I have mentioned, two miles is quite as much as it shows.

4254. (*Captain Hallett*). After you have obtained the information that the screen is parallel with the middle line of the ship, how are you going to get the angle at which the screening is?—The distance from the outer edge of the wick to the side of the screen is measured.

4255. How?—Well, in the first place I measure from the side of the lamp to the outer edge of the wick, then add the distance from the side of the lamp to the screen, and deduct from that the depth of the chock. The difference between the depth of the chock and the other measurements should, for a distance of 3 feet from the light, give 2½ inches.

4256. Four degrees?—Four degrees, yes.

4257. Now, are those measurements taken by a rule or by compasses, or what?—By rule.

4258. I mean it would be a little difficult to get a rule into those lamps and measure them accurately, because a quarter of an inch there makes a good deal of difference?—No, I do not think there is any difficulty in the matter. You can place one rule across the side of the lamp *here*, and then measure by another rule from this

*Mr. T. J. Richards.*

26 June 1895.

rule to the outer edge of the burner or of the wick. That would give you the distance quite easily.

4259. I do not fellow how you do it, because you have only one door, and you have the lens and one thing and another in the way?—The door is as a rule *here*, and the rule is placed across *here*.

4260. And then you measure the distance by squaring the two rules?—Yes, of course the door is not always *there;* sometimes it is in one place and sometimes another, but there is no difficulty practically in doing it.

4261. Do you put all the lights in place when you measure?—Yes.

4262. The spare lamps and all?—Yes. The Board of Trade have no rule requiring spare lamps. Spare lamps are as a rule carried on board vessels, but that is more particularly owing to the action of the underwriters.

4263. Do you not see the spare lamps placed?—Oh, yes, those are seen.

4264. But I mean are they measured for their screening?—Yes.

4265. Because they may not be exactly the same lamps?—Well, if there is any difference they have to be altered. The owners are requested to alter them.

4266. Where have you been lately—in London, you say?—In London, yes.

4267. Since this 4° screening came into operation?—I was in Cardiff when the alteration as regards screening came into force.

4268. You say the majority of angles had to be reduced?—No, I found that the new rule regarding the 4° angle made very little alteration in the screening.

4269. They were pretty well correct?—Yes, practically correct.

4270. (*Captain Castle.*) You said 2½° from the inside wick was equivalent to 4° from the outside wick?—No, I say that if the distance from the outer edge of the wick to the parallel line through the outer edge of the chock be 2½ inches then the 4° angle is obtained.

2471-2. (*Captain Castle*). I thought you said they were the same—that one was 2½ inches and the other 4°?—I do not remember making any remark about 4 except as to the 4° angle.

4273. (*Mr. Bolam.*) Were you a principal officer in South Wales?—No, I was the senior surveyor there.

4274. What port were you at?—Cardiff.

4275. Then you do not appear to agree generally with the evidence of the principal officer for South Wales, whose view appears to be that the Board of Trade have considerably lessened the angle of screening in the Bristol Channel district. You think the angle has remained about the same?—I did not understand that that was his view.

4276. But, at any rate, whatever his view is, your view is that the Board of Trade have practically left the angle untouched?—Yes, that is my opinion.

4277. And you speak of Cardiff?—Yes.

4278. You never measured the distance from the inner edge of the lens to the inner edge of the wick of any lamp that you ever screened?—I will not say that, but I do not remember the distance; I did not regard that as material.

4279. And therefore you cannot say anything about it now?—Indeed, I have measured it.

4280. You do now?—I have frequently measured it in order to see that the full light would get out of the lamp.

4281. That is now?—Yes, and formerly also; but I am not in a position to say the exact distance.

4282. Therefore, you can say nothing about the angle the inner edge of the wick made with the outer edge of the chock?—Yes, the angle that the inner edge of the wick made with the outer edge of the chock on the screen would be simply the angle of about 4° reduced by the angle subtended by the breadth of the wick.

4283. May I say that that is a general proposition that does not meet my question. If you have screened the inner edge of the lens to the outer edge of the chock fore and aft—at right angles to the ship's fore and aft line—and if you have no recollection of the distance between the inner edge of the lens and the inner edge of the wick, you cannot state now at all positively what angle the inner edge of the wick would make with the outer edge of the chock?—No, I cannot.

4284. Have you any record of the depth of the wick at right angles to the fore and aft line previous to the 4° rule coming into operation in 1892?—If the burner is placed at right angles to the line of the vessel then with paraffin lamps, that breadth would be about one inch; if it is at an angle of 45° the breadth would be about ¾ of an inch.

4285. That is simply a mathematical statement. But I want to know if you have any record of the depth of the wick at right angles to the fore and aft line; previous to the 1892 rule?—Yes, the breadth of the wick has been an inch for many years.

4286. Of all the lamps that you have examined?—All the lamps with paraffin burners—one inch to one and one-eighth of an inch.

4287. For all the lamps you are speaking about?—Yes, except when fitted with oil burners.

4288. You have no positive recollection of the angle the inside edge of the wick made with the outer edge of the chock?—But I can tell the angle from the outside. My recollection does not depend upon the inner edge of the wick, it depends on the outer edge of the wick.

4289. Previous to the 4° instruction?—Certainly, Yes.

4290. But all you positively say now is that you screen the lamps so that the inside edge of the lens was fore and aft with the outside of the chock?—Yes, that was so, formerly.

4291. Do you know Harvie's lamps?—Yes.

4292. Do you know whether in Harvie's lamps, previous to the 4° instruction, the line joining the inside edge of the wick, the inside edge of the lens, and the outer side of the chock, was one straight line parallel to the fore and aft line of the ship?—I cannot say that.

4293. Can you say it was not?—No, I cannot.

4294. How long were you at Cardiff before you went to London—how long were you at Cardiff after the 4° instruction was in force among the surveyors?—About 12 months, I should think.

4295. How many ships did you examine?—I cannot say—a considerable number.

4296. And at any rate you did not diminish or increase on the whole the angle of the screening; you thought you left it very much the same?—Yes, I considered that the screening was practically not altered by the new regulations.

4297. (*Mr. Scrutton.*) Do you treat the spare lamps exactly in the same way as you treat the others?—Yes, they are treated in the same way.

4298. Do you examine them exactly in the same way?—Yes.

4299. Fit them into their places?—Yes. I may say that since I have been in London I have not had very much to do with the inspection of lamps myself. I am senior engineer surveyor, and my duties do not leave me very much to do with that now.

4300. When you did take an active part in the matter, did you treat the spare lamps in exactly the same way in all particulars as to measurement and everything as the other lamps?—Yes, that is so.

4301. Exactly?—Yes.

4302. Did you find that the spare lamp always agreed with the other?—No, it required alteration sometimes.

4303. Did you see that alteration done?—Yes.

4304. Absolutely?—Yes.

4305. You did not give your certificate until you knew it was done?—Not until I was satisfied that it was done; and that has been the practice with the surveyors generally.

4306. Now with regard to the glass. Did you adopt any plan whatever to test the efficiency of the glass?—Efficiency in what way?

4307. Whether it allowed a free escape of the light or otherwise—for instance, as to its colour?—Its colour was tested by the colour we knew that it should be.

4308. Did you carry that colour about with you?—No.

4309. What did you trust, then?—I trusted to my judgment of the degree of darkness and colour that there should be, but in all cases of doubt it was compared with standard colours in the office.

4310. How did you do that—just simply hold it to the light to form an opinion?—No, the lamp was lighted.

4311. And you went how far away from it?—Took it into a dark place and examined the colour of the light under those conditions.

4312. Having nothing to compare it with?—Except in cases of doubt.

4313. You simply trusted to your impression?—To my own judgment; except, as I say, in cases of doubt, when reference would be made to standard glasses that we had in the office.

4314. Did you on board ship have anything whatever to do with the lights at any time?—In what way?

4315. When you were on board ship in what way did the lights come under your observation?—They did not come specially under my observation while I was an engineer on board a vessel.

4316. Do you attribute any of the knowledge you have to the fact that you were an engineer?—No. I of course had frequent opportunities of examining and observing the behaviour of lights while stationed in the Tyne. You see vessels approach from seawards from the pierheads, and you have as much opportunity of seeing them as if you were at sea.

4317. (*Sir E. Harland.*) I think you said that you were in the habit of dealing entirely with the inner edge of the lens as a measurement for the chock?—That was formerly, before these regulations.

4318. That is before 1892?—Yes.

4319. Then up to 1892 you had not taken any notice whatever where the wicks might be placed in the lantern relatively to the fore and aft line of the ship and the edge of the lens?—No, not specially.

4320. Did it ever strike you that there was a great difference in distance from the inner edge of the lens to the edge of the lantern in one lamp as compared with another?—There really was not very much difference at that time. Lamp makers went very much on one plan in making their lamps; and in order that the crossing of the lights might be obtained and that the lights should show two points abaft the beam, it was usual then to place the wick nearer to the lens than it is now. The result was that the wick was not quite in the centre of the lens, and the Board of Trade issued an instruction that the wick must be in the centre of the lens, and that led of course to an alteration in position.

4321. Do you think that there was a great variety in the positions occupied by the wick prior to 1892?—I do not think so.

4322. In consequence, I mean, of the variety of positions of the edge of the lens?—I do not think so. I do not think the position of the wick varied very much in lamps.

4323. You would admit that there was a good deal of chance in the matter?—Oh, certainly, there was a certain amount of variation in the position, and that of course led to the need for alteration in some cases and not in others. But what I say is that as a rule putting the chocks on in the way we did we practically got a 4° angle.

4324. Would you consider the present mode of dealing with the wick more desirable than the former method?—Certainly. There is a great deal more precision about it.

4325. Have you had experience of screening lights placed in lighthouses?—I have had less to do with those placed in lighthouses than those placed otherwise, but I am conversant with the arrangement of them.

4326. Have you ever measured your chock or set off the angle of lights in lighthouses on ships?—Yes, in a few cases.

4327. Did you find any difficulty in it. Was it equally difficult or more difficult to do than the other screens?—I do not remember having to do with lighthouses previously to 1892.

4328. Since 1892 have you adjusted the screens in any of the lights carried in lighthouses?—In a few cases only.

4329. Did you find any difficulty in so adjusting them?—Well, they are less easy to adjust than they are with an open screen. They are not so easy to get at.

4330. How did you go about making your measurements and counter-measurements?—The parallelism of the screen was ensured first, and then the distance was taken from the outer edge of the wick to the inner edge of the screen in the same way.

4331. But how did you ascertain that, seeing that the screen is not inside the lighthouse?—Well, it is much more easy to do it if you are able to move the lens.

4332. What may be termed the weather glass outside?—Yes, quite so.

4333. Did you ever remove those weather glasses?—No, I cannot say I have.

4334. And if you had, would the lens not then have still been in the way?—Yes; there is difficulty in it. I can scarcely describe generally how it is done, but we attend to the same broad principles of seeing that we get the same angle of 4°.

4335. Would you have preferred there being some little opening on the inner edge of the lighthouse so as to have measured through this opening to the wick?—I think what would facilitate it very much more would be the glass being removable, so that it could be slipped out. There is no practical difficulty in that, and it certainly would facilitate the measurement very much.

4336. I suppose you will admit that those glasses must not be very easily removed, otherwise the sea might remove them?—If you could slip them down from the top I do not think there would be any danger then. Indeed, a small screw or clip would be sufficient to keep them in.

4337. (*Mr. Scrutton.*) How did you make the dark room when you tested for colour?—We went into the top gallant forecastle and shut down the dead lights there.

4338. How far would the lamp be from you when you looked at it?—Perhaps 15 feet.

## Thursday, 27th June 1895.

PRESENT:

THE RIGHT HON. SIR FRANCIS H. JEUNE IN THE CHAIR.

Rear-Admiral ANDOE.
Captain WILSON BARKER.
Mr. BOLAM.
Captain CASTLE.
Captain HALLETT.
Sir EDWARD HARLAND.
Mr. SCRUTTON.

Mr. C. HIPWOOD, *Secretary*.

*Capt. Turriff.*

27 June 1895.

Captain TURRIFF called and examined.

4339. (*Chairman.*) You are, I think, a captain in the Merchant Service?—Yes.

4340. And at the present moment in command of the "Hogarth"?—Yes.

4341. How long have you held the position of master of a ship?—Since 1865.

4342. (*Sir E. Harland.*) Of a screw steamer?—Yes.

4343. (*Chairman.*) Where has been your experience?—Principally on the coast.

4344. The East Coast?—Yes.

4345. Between London and where?—Between London and Aberdeen.

4346. What is the tonnage of the "Hogarth"?—1,227 tons gross.

4347. Is that generally the sort of vessel which you have been engaged in during that time?—A little smaller the other vessels have been.

4348. How often do you go?—Once a week each way.

4349. You go up and back again?—Yes.

4350. Each voyage is about what?—Thirty-six hours.

4351. Do you go with passengers and cargo?—Yes.

4352. I suppose up and down that coast there is a great deal of traffic, is there not?—Very much.

4353. Which means vessels going north and vessels going south?—Yes.

4354. Besides that, at various points there must be a great deal of cross traffic?—A great deal of it.

4355. Traffic coming from foreign ports and going to Hull, the Tyne, and all down the coast?—Yes.

4356. So, I suppose, you pretty constantly meet vessels?—Yes.

4357. And very often cross vessels?—We are very seldom without seeing some.

4358. Both by day and by night?—Always.

4359. Of course your 36 hours covers, and must cover always, a day and a night?—Yes.

4360. So you have experience of both day and night each way?—Yes.

4361. Now I want you to tell us, please, what is your view about this screening of the lights. What do you say as to the present rule which requires that these lights should be screened to an angle of 4°?—My impression is they cut too close ahead.

4362. Cut too close?—Yes, cut too close ahead.

4363. So that, in your judgment, the lights ought to be screened finer?—The lights ought to be screened finer.

4364. So that they would not cut so far ahead?—Yes.

4365. Before the present rule came into force——

4366. (*Sir E. Harland.*) You say "cut so far ahead," I presume you mean so close ahead?—Yes.

4367. (*Chairman.*) That is to say you think the lights should be screened finer, so that they would not cut so close ahead?—Yes.

4368. Now before the 1892 rule came into force, what was your experience as to the screening which existed in fact. First of all with regard to what you yourself had to do, do you think they were screened finer or coarser?—They were screened finer than they are at the present time—very much so. In fact my impression is they were making a very great mistake when they altered them.

4369. What do you think was the sort of screening which was adopted before the rule came into force?—I should say something like 2°.

4370. You consider that preferable to the 4°?—I prefer that in the narrow channels which we are accustomed to.

4371. Could you tell us why you prefer the finer screening to the 4°?—Simply because you require less altering of the ship's course to show you the one distinct light.

4372. You mean that supposing, for example, you have a vessel on your starboard bow, in order to be sure that there is only one light visible you would require to alter less if you starboarded your helm slightly than if you had to port it and get across the bow?—Just so.

4373. When you say especially in narrow waters do you mean by that river or narrow waters only?—The approaches to the Thames and the Thames itself; I consider those channels are very bad.

4374. For vessels coming from the north the channel is narrow by which they approach the Thames?—It is after you pass—Cromer we will say.

4375. When opposite the Essex coast all vessels coming to the Thames from the north come through a comparatively narrow channel?—Yes, from Orfordness.

4376. You think it important especially in these channels to have the lights screened finer than 4°?—Yes.

4377. Do you yourself see any danger in lights being screened finely—do you see any objection to that?—No, I see no objection to that at all.

4378. You know what is suggested is, that if the lights are screened finely two vessels on parallel courses, not quite end on, would be green-to-green in the sense that each would have the other on the starboard hand, and if they prolonged their courses with strict accuracy those two vessels would almost touch. I daresay you have heard that suggestion made?—It is quite true in these narrow channels that we have got to contend with that on the coast; it is a close shave very often, and we must put up with it.

4379. You pass close to each other?—I say it is customary to pass each other very closely. We cannot avoid it, and I prefer having to alter slightly than having to alter at a larger angle. My idea of the large angle would be that it may do well enough in the open sea, but I do not approve of it in the narrow channels.

4380. I forgot to ask you before, do you take a pilot?—We take a pilot from Gravesend. I am my own pilot from Orfordness to Gravesend.

4381. You take a pilot from Gravesend?—Yes.

4382. Do you have your own pilot in going through these channels off the coast of Essex?—I am my own pilot.

4383. If you had your way about this matter of screening now, what rule would you like to see adopted?—Just about half what they are now—about 2°.

4384. Have you any opinion whether it is best to screen from the outer edge of the wick as opposed to screening from the middle or from the inner edge?—That I have never seen tried. I do not know how these lights would work; I have no experience of them.

4385. I daresay you know that before the 1892 rule they were screened to the inner edge of the lens, which may or may not have been screening exactly to the inner edge of the wick?—I understand that there are different sets of lamps, or rather that the wicks are differently set in different lamps; but whether that makes any difference to the light or not I cannot say.

4386. You have not, of course, yourself conducted any actual experiment?—No.

4387. I should like to ask you this. Of course, you know gentlemen who are acquainted with these subjects. What do you think is the general opinion of the practical men you have come across?—The general opinion of the practical men of Aberdeen, particularly those in the coasting trade, is that the lights ought to be shaded finer; that is the general opinion of all those I have consulted in the coasting trade.

4388. (*Mr. Scrutton.*) Do you say that is the opinion of practical men?—That these lights are too closely cut, we see the two lights too close together—or rather when the ships are too close together. We see them up to the last moment, you may say, before we know exactly how to alter. Were they cut finer a very little angle would show one light distinctly which would be more satisfactory to all of us who work the narrow channels.

4389. (*Rear-Admiral Andoe.*) You said that you preferred fine screening for narrow channels?—Just so.

4390. But you would, as I understand it, prefer the 4° screening for the open sea?—For the open sea, certainly.

4391. Then do you suggest having two kinds of screening, one for narrow channels and one for the open sea?—No.

4392. Which, do you think, on the whole, would be the better?—2° instead of 4°.

4393. Why do you think 4° would be better for the open sea?—Simply because there is more room to alter the course wider.

4394. Is it desirable? Take the case of two ships meeting each other, half a point on each other's bows, starboard to starboard, if they were screened to 4°, one would probably see both lights of the other, and, according to law, they would have to port their helm to keep clear of one another, would they not, if they saw both lights ahead, or nearly ahead?—Just so; that is where I consider the evil is, we see them so long, and the ships get so close before there is seemingly any alteration.

4395. Therefore, even in the open sea, you do not see any objection to the finer screening?—Not where there is ample room.

4396. I say, in the open sea you do not see any objection to the finer screening?—No, not a bit.

4397. Do you meet many ships on your voyages backwards and forwards passing in nearly opposite directions to you?—Well, I reckon between London and the Tyne is the most busy place in the world; we have them from Harwich and all those ports along the coast.

4398. Have you been able to notice since the new 4° rule came in that there has been any perceptible difference in the screening of ships you meet?—No further than we do not know exactly what the ship is going to do until we get close to, and I believe several accidents have happened through that.

4399. Do you find that they nearly cross your bows before they begin to alter, when they are coarser screened?—No; but they very often do approach very close before they alter.

4400. You attribute it to the coarser angle of screening?—Yes.

4401. (*Captain Wilson Barker.*) You said just now you think the old angle would be 2°?—I believe so.

4402. Did you ever take any pains to discover what it was, did you ever take any measurements?—No.

4403. You only imagined that?—Yes.

4404. You think there is a decidedly marked difference since the new rule came in?—Decidedly so.

4405. You notice it very much?—I notice there is a great difference.

4406. Because the general body of evidence seems to point to the fact that the angle of screening was greater than 4° before?—I cannot see that.

(*Chairman.*) Not all; that is the effect of some of the evidence.

4407. (*Captain Wilson Barker.*) Have you noticed whether there is any difference between the way the red and green lights shine across the bow, across the line ahead of the ship?—Yes, I have noticed in the ships that I have commanded since the alteration was made, that we can stand forward and see both side-lights of the ship.

4408. But do you find that one shows more ahead across the bow than the other, both being screened to exactly the same angle?—You can see both lights till you are very close together, and no doubt after there has been an alteration made in the ship's course.

4409. Can you see the red light more on the green side than you can see the green light on the red side?—If it is a case of seeing both lights, I cannot say that there is any difference, or that we see one light better than another. If you can see them at all it seems to me you can see one as distinct as the other.

4410. Would you see the red light at right angles to the course of the ship on the green light side more than you would see the green light in a similar position on the red light side?—No, I could not see that.

4411. You have never noticed that particularly?—I have never noticed that specially.

4412. (*Mr. Bolam.*) When the new 4° rule was issued, were your chocks cut down, or was something added to them?—My ship has never been altered since.

4413. You said that the opinion of captains in Aberdeen is that the angle should be less than 4°?—Yes.

4414. And you are in the passenger trade from Aberdeen to London?—Yes.

4415. And do you see the captains who are in the passenger trade between Dundee and London?—Yes.

4416. And from Leith to London?—Yes.

4417. Have you any idea what their opinion is?—I have no idea what their opinion is, any further than it was their impression that it was a mistake having them altered. It was the general idea that it was a mistake.

4418. Have you ever heard of anyone objecting to a larger angle of screening being made smaller than before?—No.

4419. All the objection you have heard is from these people who have had the lesser screening angle made larger?—Just so.

4420. You see there is no doubt that some ships had their lights crossing more than 4° before, and some had them crossing less than 4° before; therefore to make that 4° uniform some must have had the crossing lessened, and some must have had it slightly increased?—Of course, knowing it was compulsory I was under the impression that all ships would be the same.

4421. You have heard no one grumble that the angle has been made less than before?—No, but the general opinion is that it ought to be made less now.

4422. By "narrow waters" you do not mean rivers only?—Not exactly rivers only, but you may be passing along the edge of the banks.

4423. You mean coming south?—Yes.

4424. Therefore you call the banks off Yarmouth, narrow waters?—Yes.

4425. So that narrow waters, according to you, to a large extent, is also ocean navigation?—Yes.

4426. You do not know now what another ship is going to do with a 4° angle of screening?—No.

4427. Is not that danger quite as great in open as in narrow waters?—Yes; the only difference would be you have more room to wipe your ship off.

4428. But although the angle of screening is made smaller you are not compelled to use a smaller helm in open water?—No.

4429. (*Mr. Scrutton.*) Your vessel is 252 feet long?—Yes, that is on the keel.

*Capt. Turriff.*

27 June 1895.

4430. Do you know how far from the stem your lights are placed?—As near the middle of the ship as possible.

4431. And standing on the stem you see both lights?—Yes, I could see the lights standing on the forecastle deck about 10 feet abaft the stem.

4432. Did the Board of Trade officials know that that was the case, do you think?—Their attention was called to it on more than one occasion, and not only that, but the green light especially was a great nuisance to us on a dark night shining over the rails.

4433. And still they did not alter them?—Still they would not hear of any alteration.

4434. Have you tested the screening to know whether it is 4°?—Yes, that has been done.

4435. And it is 4°?—Yes.

4436. Have you any idea how many vessels you meet going north, ordinarily?—Putting it down in round numbers, I might say 100.

4437. Constantly meeting?—Yes.

4438. And in the same way as you come south?—Yes.

4439. (*Sir E. Harland.*) In your answer just now you say that a little abaft the stemhead you could see both lights; do you think that you saw the wicks of those lights, or was it only the outside of the lens that you saw?—Possibly it may have been only the outside of the lens, but the lights seemed to be perfectly distinct.

4440. Have you dioptric lenses?—Yes.

4441. Do you think it is possible that it might have been the outer edge of the lens you saw from the forecastle?—It is quite possible; it is a difficult matter to see the flame through those glasses.

4442. The effect of the prisms being to distribute the light generally through the lens?—That would be so.

4443. Your side-lights are pretty well amidships and your masthead light is pretty well forward?—Just so, on the foremast.

4444. That being so, a vessel whose path you were crossing would see your side-lights at a considerable angle abaft the masthead light?—Yes.

4445. Do you think that is an advantage as giving an indication to the other ship as to the course you are steering?—I think the lights being abaft the foremast is an advantage.

4446. That is to say, at the first sight you are able to form immediately a pretty good idea as to what course she is on?—Do I understand you to mean the lights, or only one light?

4447. I mean the masthead and one light, so (*describing with a model*)?—That is a distinct advantage.

4448. You are able at once to see in that position, that *this* ship is going *that* way?—Yes.

4449. And if the lights were now, as I am placing the model, you would at once conclude that as this angle is finer she is coming more nearly towards you?—Coming more in a straight line.

4450. You would then prefer that all ships, if possible, should have their masthead and side-lights arranged something on *that* principle (*describing*)?—Just so, but you would have to show a great angle to get *this* light in the position in which it is now showing.

4451. In other words, to accomplish this, you think it would be desirable and necessary that your side-lights should be pretty well amidships?—Just so.

4452. Assuming your mast head light is pretty well forward?—Yes.

4453. It is to give an angle of 45°, or more?—Yes.

4454. If such were the custom of placing ships' lights it would be a great advantage?—Yes, it would be a great advantage.

4455. Some ships are fitted with the lights on the after part of the forecastle?—That is so, and with the masthead light abaft it is very apt to lead ships astray if the ship is making very little headway.

4456. Which way do you think they should be fitted?—On *that* principle (*describing with the model*).

4457. Do you know many cases where the side-lights are immediately below the masthead light?—Very few, the other is by far the most common.

4458. And you would be glad if that were to be the rule?—I should like it, certainly.

4459. (*Rear-Admiral Andoe.*) You said just now that narrow waters were narrow channels where you have not got free space to navigate or manœuvre your ship as you are confined by the narrowness of the channel to a small helm?—Just so.

4460. Is that what we are to understand you think is a narrow channel?—Yes, we very often come through Yarmouth Roads, and the approach is very narrow indeed and dangerous.

4461. You said—perhaps hardly meaning it—that you consider it open ocean navigation; but a seaman speaking of open ocean navigation means to say that he has got ample room for manœuvring his ship?—That is when you are well out at sea; but these narrow channels are placed in the North Sea.

4562. But the question was put to you, whether you did not consider these narrow channels in the North Sea to be ocean navigation. I ask you as a seaman whether you consider being in a very narrow channel, although it may be in the North Sea, is ocean navigation?—Well not exactly the same; but I think Mr. Bolam was a little exacting in that part in asking whether I considered a narrow channel was confined only to rivers. It was simply upon that that I gave that answer.

4463. As a seaman you would not call it open ocean navigation if it referred to a narrow channel?—Certainly not. That is what I meant.

4464. Therefore you would treat a side-light in a narrow channel, although it was out in the sea, exactly the same as if it was in the Thames?—Just so; certainly.

*Mr. C. Hall.*

Mr. Chas. Hall called and examined.

4465. (*Chairman.*) I think you are a member of the Institute of Electrical Engineers?—Yes; also of the Naval Architects, and an Associate Member of the Institution of Civil Engineers.

4466. And you hold some office in connection with the P. and O. Company?—I am chief of the Repairs Department, having to do with the upkeep of the Company's steamers, and the electric work has come into my hands as a specialité. All the lighting of the fleet has been carried out by me.

4467. So you are well acquainted with the electric lights used by the P. and O. vessels?—Yes.

4468. Are most of the vessels of the P. and O. fitted with electric side lights?—All new ships; all since about 1889 or 1890. A trial was first made of one large incandescent lamp in each side light having the "focus" filament advocated by Chance Bros., and with the colours in the glass; these proved failures, and I then designed a group of five lamps arranged thus (*exhibiting specimen*); this gives 80 candle-power, and if one lamp fails the loss of light is not important; these have been largely used, and have been highly commended.

4469. (*Sir E. Harland.*) Is this a side-light?—Yes, it is intended to go in the place of the oil lamp as made by Chance; it fits into the gimbals, in the same place.

4470. (*Chairman.*) Identically the same lamp?—All the hangings, the same reflector as before; but in this the electric light takes the place of the oil-lamp. In the case of one filament failing you still have the light of the other four filaments.

4471. What is the power?—It has a total of 80 candle-power; I had it in my mind to increase it so that it might be visible at long distances.

4472. Do you have 80 for red as well as green?—It is not needed so much in the red light; in some cases three lamps only have been used for the red light.

4473. (*Mr. Scrutton.*) What is the size of each?—They are 16 each.

4474. (*Chairman.*) Three would be 48?—The incandescent lamp is a special one I had made for the purpose; it is, you will observe, of very compact form.

4475. (*Rear-Admiral Andoe.*) Each lamp is 16?—Yes. This is not a long-lived lamp, but answers the purpose

of making the thing compact. Unfortunately the arrangement of five lamps in a group is now being objected to by the Board of Trade; it is a little too large in diameter for them, and, I understand, crosses the bows so as to affect what is called the "dark lane."

4476. (*Chairman.*) Before we come to that what sort of lights are now actually used in new vessels of the P. and O. like the "Caledonia"?—It is in this form on the "Caledonia" at the present time; but I understand that we shall have to alter it and substitute one with only two lamps.

4477. Are there any vessels which are used with the two?—Some of the cargo vessels have only two lamps.

4478. Do you put them side by side?—No; one lamp is in focus and the other one behind (out of focus), as a standby. It is under the special permission of the Board of Trade we have the second light at all. They prefer to have only one; I do not say this from my own knowledge, I am so informed by Captain Angove who has communicated with the Board of Trade, and he says that the tendency is in favour of one lamp; which, in my own judgment, is unsafe.

4479. Because if that filament breaks?——There is a darkness.

4480. In this case if you triplicated the light, at any rate you have two if one should go?—Yes.

4481. When you have got all these in, what breadth does that give?—2¾ inches, the outside of the filament, —as near as possible 2¾ inches over the outside edge.

4482. That is of course too much?—Half an inch too much.

4483. (*Mr. Bolam.*) How much is it *this* way—about two or what?—That is not 2 inches, 1⅞ inch I should think; if the filaments are flat you might make it still less.

4484. (*Chairman.*) There would be difficulty in arranging it, but you could have two lamps at any rate and yet exhibit an area of only 1 inch or 1½ inch?—It means an undesirable filament. You can get a light of 100 candle power in one lamp if you wish; but it would necessitate a large filament, which would tend to break itself by its own weight; it is not a filament that would last, and is not so safe a filament as those of 16 candle power for that reason.

4485. Can you tell me this. Take the ordinary oil lamp such as we suppose the P. and O. probably used before the electric light was introduced. What candle power would they give?—I cannot speak from any measurements, but I should think 18 or 20 candle power. I can only speak from conjecture.

4486. Does that compare measure for measure with these lights; would an electric light of 40 candle power be really double the power of a 20-candle oil-lamp?—I think so; the Ediswan 16 candle power lamp is an absolute 16, if the lamp is new.

4487. When you speak of the power of electric light, is the candle power the same unit as for an oil lamp?—Yes. I think it can be depended upon that this lamp is of the power of 16 standard candles. It is a new lamp, but this result, of course, supposes that it is worked up to full power. After a little time the light-giving power of the lamp will go down.

4488. Then why do you think it necessary to have the electric light produced so very much more powerful, to double and even treble?—Owing to the increase in speed in the new ships. Two ships approaching each other at 18 knots, have evidently less time to see the lights than in the old days at a speed of 10 knots.

4489. Your reason is not in fact connected with the inherent character of the electric light as opposed to oil-light, but rather on account of the altered conditions of navigation?—As I understand officers are always anxious to have the electric light in side lights on that account, and for the reason I have stated, the increase of power (particularly that of the green light) was much appreciated by our officers.

4490. Supposing it was thought sufficient to have electric lights, of say 40 candle power, so as to be well over the old lamp, and not much over it, would there be any difficulty in providing them so as not to have a greater breadth, than somewhere about 1 inch or 1½ inch?—There would be no difficulty, but there is an objection in other directions, which I will tell you of. An accident occurred in my own experience. We had (as previously mentioned) some red and green 80 candle power lamps, having the colouring in the glass of the bulbs, the filaments like this (*describing*), the ordinary reflector behind, and we found that the heat rays were focussed by the reflector upon the glass and the vacuum drew in the glass like the bottom of a bottle, the glass being softened by the excessive heat.

4491. It is clear you ought not to have it?—Not all the power in one lamp.

4492. (*Sir E. Harland.*) With the filament inside?—The filament remained uninjured in one case; I have not the lamp; it was handed to Mr. Swan and unfortunately he never returned it.

4493. (*Mr. Bolam.*) The candle power of that would be 200, I suppose?—No, only 80 I believe; I am only speaking from recollection, but I can ascertain accurately if you wish.

4494. (*Chairman.*) What power would you think sufficient; what is the power of the lamps you have shown us?—16, the bulbs are rather small for this power and they are easily broken by spray or even a cold draught.

4495. Could you put two of those into a larger glass?—Yes, I have seen double filament lamps, but have not used them (*double filament lamp with screw connexions produced*). We use the ordinary 16 candle lights in other parts of the ship; we have no screw couplings, they shake loose.

4496. What breadth of filament is necessary? Suppose you designed two lamps each of 16 candle power, what breadth of filament would you require?—That is a matter for the designer, and one I cannot accurately answer. I do not call myself a practical lamp maker.

4497. (*Sir E. Harland.*) What is the diameter of that filament?—It is about 1¼ in. over the curl.

4498. (*Mr. Bolam.*) That is marked 100.

4499. (*Captain Hallett.*) 100 volts?—Yes, and 16 candle power.

4500. (*Mr. Scrutton.*) Sixteen each?—Yes, a double filament lamp, the danger of which is unfortunately that if one filament breaks it will most probably cause the breakage of the other by "short circuiting" it.

4501. (*Chairman.*) I should like to ask you as to that?—If one breaks the other would almost to a certainty break also; in this respect it is in my opinion less reliable even than the "focus" filament as advocated by Chance.

4502. I am afraid you have crushed my hopes as regarded this. That seemed to have solved the difficulty somewhat, but I am afraid now it will not do. You have two filaments, each of 16 candle power, put into an area which exceeds the length of the inch and quarter?—If one breaks the other would break immediately. The breakage of the one would almost certainly cause the breakage of the other.

4503. So you think it better to have two separate lamps?—Yes.

4504. Still if you had two separate lamps it could be so arranged that for the purpose of screening them—you could so arrange the area that in screening it would come to something like 1¼ inches?—Screening is rather out of my depth.

4505. I only want to know your view?—It is a thing I have endeavoured to follow up, but I cannot see day-light yet.

4506. Would there be any difficulty in having two lamps, each of 16 candles, one behind the other?—It is, as an actual fact, now the practice to use two lamps so placed in several of the cargo ships of the P. and O. Co.

4507. You do carry them in the cargo ships?—In recent cargo ships we have had two lamps in that way by agreement with the Board of Trade, who prefer the two lamps rather than three or five.

4508. (*Mr. Bolam.*) You mean one behind the other?—Yes; it is a special concession of the Board of Trade.

4509. The light of one lamp is practically transparent through the light of the other for all practical purposes?—As I understand the front is in focus, and the other is simply put for our satisfaction as a matter of safety.

4510. (*Chairman.*) In order that if anything went wrong there would be the other to fall back upon?—Yes.

4511. Do you think it important in the case of an electric lamp to have what you call a stand-by lamp,

*Mr. C. Hall.*

27 June 1895.

so that if one breaks you have the other?—I always advocate at least one spare lamp.

4512. As a matter of fact, do you know whether these are apt in practice to break. We know in a room when they give way they give way very suddenly?—Our Edison and Swan lamps give an average life of 2,000 hours, that is to say they last as a general rule for nearly two years.

4513. Is there any great variation?—At the end of their life they get black, and you have not 16-candle power, but for 2,000 hours it can be got with but trifling variation if the lamp is good. The average "life" spoken of just now is drawn from observation of about 12,000 incandescent lamps about one half of which are removed annually.

4514. Are some of them liable to collapse before that time?—Yes, of course, some break sooner than others from various causes.

4515. Electric lighting is near enough to everybody in a house, and it is the experience of almost everybody that until they have done their work they do not collapse?—In some degree it depends upon how the lamp is stored. If the filament is at all soft it will sometimes take a permanent "set" so that it touches the glass, and goes at once. This is a reason for always keeping lamps in a vertical position. Sometimes, if carelessly handled, the lamp is destroyed by a blow, or if put on the current with the filament "hitched" on itself, it will break at once.

4516. Do you know whether the action of the ship affects it?—I do not think that has any effect at all, if the carrying is good. As a matter of fact, I know of some old lamps in use now which, I believe, are upwards of 5,000 hours old, and they have not blackened very much.

4517. I have no doubt you have a strong opinion that the electric light is preferable for side-lights?—As far as I am individually concerned I prefer them, and I find that on board ship everybody likes to have them; as far as my own duties are concerned they give little extra trouble. It is certainly in the interests of safe navigation to provide electric side lights of increased power, provided they are reliable.

4518. One might fairly expect that the Mercantile Marine will adopt the electric light more and more?—Yes, it has been adopted very largely already for side-lights.

4519. Now with regard to that light, is there any objection made by the Board of Trade, except in respect to the extreme breadth?—The objection relates to the width alone, I believe. The commanders are all in favour of it; they seem to be very pleased with it. The plan is not patented and I have nothing to gain by blowing its trumpet, but it appeared to me to be a good mode of meeting the difficulty, and after a great deal of thought and experiment I induced my directors to try it.

4520. I see that answers the purpose, always supposing the light is in exactly the same place?—Yes.

4521. Would it not collapse if a screw got loose?—Yes, but there is no chance of its shaking loose.

4522. Then on what does it hang?—In the light-house; Chance Bros. provide the excellent arrangement in which it fits.

4523. (*Rear-Admiral Andoe.*) Do all these lamps burn at the same time; is that the idea?—All the five lamps are intended to be in use in a green light; but in a red light only three really are required.

4524. But all burning at the same time?—Yes.

4525. Kept as a reserve so that you do not rely on one?—If one breaks you have the others to fall back upon, that was my idea, and there was no great diminution in effect if one lamp out of five breaks.

4526. How are the electric lights fitted in the P. and O. ships, in the old lantern?—No; in all the ships which have this pattern it is in the gimbals in a light-house.

4527. Are all fitted with light-houses?—All the large ships were fitted with light-houses.

4528. But in the smaller ships?—In the smaller ships the electric lamps are fitted in the copper lanterns.

4529. In the ordinary lantern?—Yes; I should like to get away from that.

4530. Not a specially made lantern?—No.

4531. What sort of a lamp do you fit in these vessels that are not specially fitted for it?—It is used like *this*, on two holders, holding two ordinary incandescent lamps, and it has a reflector, I think, fixed to the base.

4532. What power lamp?—16 candle-power.

4533. All 16 candle-power lamps?—Yes.

4534. How are they placed in reference to the lamp there; is one behind the other?—Fore and aft.

4535. One behind the other?—Yes.

4536. What report do you get of them; are they satisfactory, speaking generally?—That question I can scarcely answer. It comes more in Captain Angove's province. He is the superintendent, and all the arrangements about these particular lamps pass through his hands. He has negociated with the Board of Trade in the matter. As the result of those negociations, the two lamp arrangement has been produced to supersede my five lamp arrangement.

4537. I suppose the objection of the Board of Trade to it is, that it does not comply with the proper angle of screening?—It is too large an angle.

4538. (*Captain Hallett.*) Would it be possible instead of having the filament bent to bring it in at the top and bottom of the lamp quite straight?—It would completely alter the connexion. You would have to make a connexion above and below.

4539. You could make it so as to get a straight filament?—You would have to alter the whole—to alter the whole design of the holder in order to do it—you would require two instead of one. Of course, it can be done, an electrician can do anything of this kind.

4540. I want to know whether you could manage with a straight filament instead of a bent one, so as to get a distinct line of light?—Quite so.

4541. But with that you would not get the full candle-power; you could not get the 16 candle-power in this limited space?—No, you could not.

4542. It would be too long?—It would increase the length to about eight or nine inches.

4543. But by putting in two or three filaments you could get a certain light which would cover a large space. But I suppose the placing of many filaments close together has this danger, that if broken the least thing makes them move, and if you multiply filaments they are very likely to touch one another?—Yes.

4544. And then they show a certain tendency to break?—They break.

4545. Could that be avoided?—Yes.

4546. Do you think it would be possible to make one in that way?—Yes, I think it could be done.

4547. I mean so as to give you the proper amount of light?—It is a matter for the lampmaker to answer. I should not like to guarantee the light of the lamps, but it is a possible thing to do, I should say.

4548. (*Chairman.*) Perhaps you will tell me this: Does the power of the lamp vary with the length of the filament?—And the substance of the filament as well, it is a matter of how much incandescent area you have.

4549. So you could get it either by length or by breadth, as you like?—You could have the filament straight up if you like. It involves a connexion here, and another one at the other end. I do not quite see at the moment how it could be managed; it would be eight or nine inches long if you wished the filaments to have 16 candle power each.

4550. (*Captain Hallett.*) Do you remember if your lamps had a second lamp which lights up on the other one going out?—No, I have tried that, it is rather a complicated arrangement.

4551. You have not fitted them?—No, I do not consider such an arrangement suitable for work of this kind, exposed to salt water. Even in the lighthouse you get the edge of a glass leaking at times and admitting spray. A glass is broken occasionally, and salt water coming in gives a lot of trouble. Salt water is the greatest enemy with which electricians have to contend on board ship, and in presence of salt water I like everything as simple as possible.

4552. (*Mr. Bolam.*) How long does it take, supposing one of the filaments is broken and you have discon-

nected the lamp, to remedy it with another?—Not two minutes.

4553. So that at the worst it is a question of two minutes. It takes far less time than if one of the oil lamps went wrong?—I should think so.

4554. You do not know anything about screening I understand?—No, it is not a subject I can offer an opinion upon.

4555. You would not know whether it is owing to the heat on each side of the breadth of light that throws the lights across the bow?—I am not aware.

4556. (*Sir Edward Harland.*) I suppose your notion of these five lights is in order to mass together a greater amount of luminous power?—Quite so.

4557. From some points of view one lamp must be immediately behind the other?—It is not quite so you will find, the lamps are all in "echelon."

4558. Suppose that this lamp is immediately ahead of me, and I see those two lamps exactly in line with each other, I gather from you that the light from these two incandescent lamps would be double that seen from one?—I should say so, because it is all collected and thrown out by a large reflector—a very accurate reflector.

4559. Supposing there was no reflector?—With no reflector you would not get the same result.

4560. That is to say, if one of these be 16 candle-power in every direction, then if you were to put another 16 candle-power behind that, would that be equal to 32 candle-power?—No, I should think not, if one lamp was immediately behind the other, but in my arrangement you will notice that the lamps all clear each other.

4561. Is it not generally conceded in oil lamps that duplicate burners give you a double light?—An all-round light probably.

4562. But does it not give you, as it were, one flame passing through the other?—I could not answer that without experiment, I should not like to guarantee that.

4563. I understand the Board of Trade object to your lamp as being too broad?—Yes.

4564. Then does that mean that while that which is say two inches is objected to, still the Board of Trade do not object to ordinary lamps of an inch and three-quarters?—As I understand it this is almost half an inch too wide.

4565. It is the half inch extra width they object to in this light?—That is as I understand it. I have not seen the Board of Trade officers about it myself. I believe Captain Angove can tell you more than I can.

4566. You have three of these in the red and five in the green. What would your notion be of the efficiency of the light, supposing that you were to place three of those exactly one behind the other in a line with the keel?—I do not know what it would come to. It is difficult to express an opinion until one has tried and tested it. My preference would be to put them in a triangle.

4567. Supposing you had them in a triangle what do you estimate the width would be then?—An inch and three quarters at the very outside.

4568. Then would that comply with the Board of Trade requirements?—I should say it ought to.

4569. Have you suggested that?—No, I have not, it has not occurred to me until now, and the matter is in Captain Angove's hands.

4570. Do you think it possible that Captain Angove has considered this mode of having a triangle light?—It is not at all improbable Captain Angove has spoken of that, but he has not told me so.

4571. If you had the three lamps, one behind the other, would that not give you as concentrated a light as possible lengthways with the keel of the ship?—The difficulty would be that only one of the three lamps could be in the focus of the reflector. My preference would be to put three lamps in a triangle and let the centre of the triangle be in the focus.

4572. But as far as throwing a strong light ahead is concerned, would the reflector not do its duty to those three lamps as in the ordinary lamps?—If it is accurately made—if it had only one possible focus, two must be out of focus.

4573. But in view of these lamps not being required merely to show a light directly ahead, but also to show to two points abaft the beam, would a reflector be misplaced if the three lights were put with the object of throwing the strongest possible light ahead in one narrow film of light; do you think that would be gained by so placing the light from the three so that it would be generally reflected all round at the various points of the compass?—It is a thing I should like to try before I gave an opinion. A hasty opinion on such a subject would not be prudent.

4574. May I ask you why you have these lamps hung in gimbals?—The gimbals are part of the outfit of the oil lamp, and my arrangement was designed to go into the socket which the oil lamp had previously occupied.

4575. Is this an appropriate light for the mast-head light?—Two ordinary 16 candle-power lamps in a line fore and aft on the mast-head.

4576. Does the mast-head light not show round three-quarters of the circle?—I cannot say what arc of a circle it shows, but they are approved by the Board of Trade.

4577. Then why have you one incandescent light for the mast-head as against five for the side-lights in view of its being as important?—I have not spoken of one. We have a pair of lamps in fore and aft position.

4578. Then it is two lights in the mast-head light?—Yes.

4579. Why have you two in the mast-head light when you suggest three or five for side-lights?—Because the coloured glass in the side lights absorbs more than the clear glass of the masthead light, the green especially.

4580. Suppose one of these two fails?—In the event of one failing the other remains effective—16 instead of 32 candle-power. I understand that there is not the same necessity for a strong light.

4581. Is it not as important?—That is a point on which I can express no judgment of my own; my attention has been principally directed to the improvement of the side-lights. In the mast-head light I have heard of no difficulty.

4582. (*Chairman.*) One thing I heard you say, that you should like to get rid of the old form of lantern?—Yes, this metal connection. It is undesirable to put an electric light in the neighbourhood of more metal than you can help, and an electric light fitted in a timber box would be in my opinion a preferable arrangement.

4583. You think it would be desirable not to utilise your ship's old lanterns?—I do; it is the same sort of thing as putting electric lamps on gas standards.

4584. (*Captain Hallett.*) You would prefer a wooden lantern if placed in the lighthouse properly protected? Yes, and the ordinary lamp on the top—each with its own screen.

4585-6. (*Mr. Bolam.*) What is the smallest width of the filament of one of these—I have the five and the two this way; can you give me the width?—It is as near as possible ⅛ in. out-to-out in a diagonal direction at the widest part of the filament.

## Wednesday, 3rd July 1895.

PRESENT:

THE RIGHT HON. SIR FRANCIS H. JEUNE IN THE CHAIR.

Rear-Admiral ANDOE.
Captain WILSON BARKER.
Mr. BOLAM.
Captain HALLETT.
Sir EDWARD HARLAND.
Mr. ISMAY.
Mr. SCRUTTON.

Mr. C. HIPWOOD, *Secretary.*

*Mr. W. H. Laslett.*

3 July 1895.

Mr. WILLIAM HENRY LASLETT called and examined.

4587. (*Chairman.*) I believe you are a Liverpool surveyor for the Board of Trade, are you not?—Yes, and also a consultative officer for Liverpool and the northern ports.

4588. When did you join the Board of Trade?—I joined it early in 1876.

4589. Before that time what was your position?—I was ship-building manager of a ship-building firm at Hull.

4590. For some years I daresay?—Yes, five or six years.

4591. And since that time you have been engaged in the service of the Board of Trade?—I have.

4592. At Liverpool?—Yes.

4593. Where else?—Our district extends from Barmouth to Silloth, but I have always been stationed in the Liverpool district.

4594. Then is it your duty to survey ships on their first voyage before they go to sea?—We survey them at any time.

4595. I should rather like to know what the ordinary practice is. When ships are first built do you survey them then?—Yes, before they are registered.

4596. Then afterwards what do you do; do you survey all ships that come into Liverpool?—As vessels come in we visit them and inspect them from time to time, noticing anything that is amiss and getting it remedied.

4597. Do you inspect those belonging to other ports as well as Liverpool?—We inspect all British, including of course colonial vessels as often as practicable.

4598. Do you inspect foreign vessels at all for any purpose?—Only when called upon; not in the ordinary way of work.

4599. So that in that way, I suppose, year by year a very large number of vessels pass under your observation?—Yes.

4600. Whenever you inspect a vessel do you always inspect the lights?—Always.

4601. I think you have looked into some statements that have been made by Captain Wade who was called as a witness here, have you not?—Yes.

4602. The first one I see is Question 3766:—"Have "you any special knowledge of the effect of side-lights "when screened to that angle?—I have; the ships "which belong to our firm are 14, and I will give you "the date of their screening respectively. Twelve of "those ships were formerly screened parallel with the "line of the keel, and they have all been altered "by the Board of Trade instructions to a 4° angle. "Ten of these ships carry passengers and two are "cargo boats. The two other ships to make up the 14 "are new vessels built since this regulation has been in "force, and I did not quote them; they are screened to "the 4° angle. I may say that these vessels were "formerly screened to the outer edge of the wick, "parallel with the keel, and since then the chock "has been reduced 2½ inches to give the 4° angle. The "effect of this alteration has been that I have observed "both side-lights on the forecastle head of three of "these ships, one being especially apparent owing "to the superior quality of her lamps, the largest "and best lamps made." Now, have you any observation to make upon that?—I cannot possibly ascertain the accuracy of the statement as to taking 2½ inches off the chocks. It is a fact that the chocks have been reduced but the amount given I cannot get from any of the engineer surveyors who have done the work. They have not kept any record.

4603–7. Have you any reason to doubt from any information you have obtained the accuracy of Captain Wade's statement?—I have great reason to doubt the accuracy of the amount of it. The surveyors that I have seen who have to do with most of these vessels particularly assure me that 2½ inches is a great deal too much; that it was more like an inch or an inch and a quarter; but I cannot gather definite information at all.

4608. Then Question 3794. In speaking of the "Lara," the witness had said "but I have frequently "in a river gone aground on the banks, which was due "to the fact that you could not see anything with the "light illuminating the ship herself. 3794. (*Mr. "Ismay.*) Across the forecastle?—Across the forecastle "The ship was altered, and 2½ inches came off the "chock at the end of the screen, and she ran for "12 months like that; she was re-surveyed, and the "Board of Trade Surveyor on the completion of his "survey instructed me to take another half inch off the "chock, which I declined to do, and it has not been "done yet. I had very serious thoughts of putting "a large piece on to the chock because of the diffi-"culty that we got into through the way that the "ship's lights were screened. They show me the "danger we are being led into . . . . There is "one other ship the 'Creaden'; I measured her lights "and she is an altered ship, and I find, as she stands "now altered, that she is screened to 4 inches to "the inside of the wick, or to 5 inches to the outside; "both her side lights are plainly visible 70 feet ahead "of the lights." What do you say about that?—With regard to the "Lara," the chock is a big one. It is rounded at the top, and it twists. It is rather misleading. It is not parallel in thickness up and down. Why it was made this shape I cannot tell. It would have been better if it were parallel up and down and thus made the conveyance from the entire outer surface of the chock, or if it tapered uniformly top and bottom.

4609. Not parallel in thickness up and down?—No; and I think it wants a little bit off the bottom of the chock to make it exactly the 4°. Why it should have been made in that way I cannot say.

4610. Then he says that the 2½ inches came off the chock at the end of the screen and ran the vessel for 12 months like that, with the 2½ inches taken off. Was the original 2½ taken off as far as you know?—That is the point I cannot ascertain for certainty; the chock was a pretty big one; even now it is 5⅝ of an inch thick.

4611. In order to give her 4° screening?—Yes; therefore it must have been 8 inches originally if he took 2½ inches off.

4612. Then it is the case that some ½-inch was taken off afterwards, the object being, as I understand, to make the chocks uniform?—Yes.

4613. Then as to the screening of the "Creaden"?—The "Creaden" was seen in Liverpool and the report was sent in as to her convergence being irregular, a request being made to the master to put it right. The fact is that the surveyor was removed from Liverpool not long afterwards and the vessel has not been seen since really. I have seen the vessel now myself and found that the two screens are not alike still, but they have not been touched at all. There is no appearance of a blow having been struck upon them, and Mr. Horne,

the Superintendent, informed me that they have never been altered. This is what I found; the starboard screen is nearly parallel to the middle line; the port screen is not, it stands outboard an inch at the fore end. In addition to that, it is not vertical, it falls outboard. Then there is a play of $\frac{3}{16}$ of an inch in the round hole that the davit goes through the rail. Then there is a play of $\frac{3}{16}$ of an inch in the screen itself at the end of the davit.

4614. (*Sir E. Harland.*) Is that a screen which moves?—Turning outboard.

4615. On the captain's bridge?—No, it is underneath it.

4616. That is amidships?—Yes. Then there is a further play of half an inch in the lantern itself when put into its position and it has to be secured by lashings; with all these irregularities it is impossible to get an accurate measurement of the angle twice the same. I found it so, and I measured it just as it was, and I found that the port screen converged $4\frac{1}{2}°$ and the starboard screen converged $5\frac{1}{2}°$. I measured it in every way, athwart ships, and I sighted it from the bridge, in order to get it as accurate as possible. I am perfectly certain it does not converge to 8°, and Mr. Horne told me it had not been touched, and certainly there was not the mark of a blow on it. The paint looks as if it had been untouched for years.

4617. (*Chairman.*) Now, as I understand you, although in the position you had screened the lamp it was $4\frac{1}{2}°$ to $5\frac{1}{2}°$, the lamp might have been at a different time so placed that it would give a larger angle of screening. You said there was some play in the lamp?—Yes, but the screen and lanthorn not being either rigid or upright will always involve variations in measurement as it is Under any circumstances this will all have to be allowed for. The whole thing hangs over.

4618. Did you put it in that condition?—I put it in the worst condition I could.

4619. And that gave $4\frac{1}{2}°$ and $5\frac{1}{2}°$?—Yes.

4620. I do not say it is anybody's fault; I only want to know the fact. Was that lamp with the screen in that condition passed by the Board of Trade?—No, it was not passed; the surveyor who visited the vessel, Mr. Taylor, had unfortunately been removed from Liverpool, and he omitted to make a note in his book that it was not so altered; but he appears to have been under the impression that it was altered.

4621. As a matter of fact, it was by a mistake?—Yes, but it was not 8°.

4622. Now in answer to Question 3807 Captain Wade said: "Previous to the Instructions to Surveyors of "1892 I have never known a Board of Trade Surveyor "to measure any chock or light screen, or anything "connected with it, with the exception of examining "the lamps when they were unshipped to see that "they were efficient articles. I have never, and my ex-"perience at sea has been in passenger vessels—vessels "which hold a passenger certificate from the Board of "Trade—up to this period known a Board of Trade "Surveyor taking and measuring the screens or any-"thing connected with them in passing his survey." What do you say about that?—The answer to that is that there never has been the slightest variation in the practice of surveyors in regard to light screens. The screens have always been placed fore and aft, parallel to the centre line of the ship, and that has always been obtained by measurements from the middle line. If on examination screens are found not parallel it is not, however, always the practice to insist on alteration of them. The line from the outside of the chock to the inside of the lens has been then made parallel with the centre line of the ship, this has been done to save expense in such cases. I have never known of any variation in that practice.

4623. Before 1892 was it the practice of the Board of Trade Surveyor to measure the chocks?—Always.

4624. And since that time has it been the practice to take these measurements on passenger vessels?—There has been no variation whatever since 1892, except that the screen formerly was 3 feet before the lantern, and now it is 3 feet from the centre of the flame, and the angle is defined. During my ship-building time, and during the 20 years I have been surveyor I have never seen the slightest variation, and recently I have seen Mr. Williams, of Liverpool, Mr. Hoar, Mr. Dixon, Mr. Watt, Mr. Buckwell, Captain Jeffery, and Captain Franks, of Liverpool. In Ireland I have seen Captain Sconce and Mr. Gloss; and in Cardiff I have seen Captain Chalmers, Mr. Sloggett, Mr. Mayor, and Mr. Sheers. I have seen them within the last week and in every instance I have allowed them to give me just their definite statement; and as we were all trained under the one system I can assure you there has never been the slightest variation in our practice.

4625. What Captain Wade seems rather to suggest is, not that the system was not the same, but that in point of fact the Board of Trade Surveyors have not devoted much attention to the screening?—It is wholly untrue. I may say that before a ship can be registered a surveyor has a little book in which there are printed notes, and he has to fill up the book, and there is a page appropriated to lights, and this always has been so. I allude to what is called S. 64.

4626. Now at Question 3879 he was asked:—"Then "I suppose that you recognise that in a vast number "of ships it is the common practice to place them with "the lights in lighthouses particularly in modern "times?—Yes, I think I can give a very fair "reason why that is done. Probably a third of my time "is spent in ship-building yards, looking after new "work and repairs that we are doing. I have noticed "that the Board of Trade have entirely set their faces "against lighthouses being placed amidships or any-"where amidships to the extent of refusing to pass "them (upon what ground I do not know), and that "has necessitated this, that the builders invariably "say, 'Well, just let these be put forward—it is a "'very good position, and there will be no trouble "'with the Board of Trade,' and by that means they "bring a pressure upon the owners about putting "them there. Many of these owners are not practical "men, or have not much experience of ships them-"selves, and they accept it, as the Board of Trade say "that is the position, and in fact they go further any "say they will not pass them if they are put amid-"ships." What is the practice of the Board of Trade with regard to the position of lighthouses?—The Board of Trade does not fix the position of the lights at all. It is quite contrary to the Board of Trade instructions for a surveyor to dictate where the lights should be carried at all; and in practice the surveyor never does. As far back as March 1876 the Board of Trade instructed surveyors to this effect. The instructions are that they shall be placed so that they show a clear light ahead free of all obstruction, and if abaft the main beam of the ship they shall be brought out to show clear of the main beam; and in practice the masters themselves fix the position. All we do is to see that there is no possibility of anything happening to obstruct the vision forward. I have myself many times had lights, when carried amidships, lifted higher up in order to be clear of obstructions, but I never myself objected, and I never heard of anyone objecting to lights being amidships. You see that statement is what the builder says, he does not say that the Board of Trade official ever said it.

4627. Perhaps it may be an entire mistake, but do you know is there anything that might have suggested that view to Captain Wade, or anybody else?—Well, it may possibly have been suggested by the lighthouses being put amidships and then objected to because they were not high enough up. I have known several cases where the lighthouses have been amidships, but the lights have not been high enough up. In point of fact they were only so high that a man could stand right in front of them. I have seen lots of these lighthouses like that, and then after the owner has gone to the expense of having them constructed he cannot use them. We have been obliged to step in and say: "If you are "going to have them there you must have them "higher up," and I can mention several vessels where the lighthouses are not used at all because they are not high enough up above the deck, and both men and fittings can obstruct them.

4628. In the same way he is asked again at Question 3892: "Then so far as sailing ships are concerned, you "do not think that where that is so it is with the "object of keeping these lights from being blinded "by the canvas?—Of course that argument applies "with more force to a sailing ship than to a steamer; "but my view of it is this, from the actions I have "seen of the Board of Trade Inspectors themselves, "that those lights are placed forward so that they "should not be seen on the ship herself, for if the "same lights were put amidships and screened to "a 4° angle they would both be visible on the fore-

*Mr. W. H. Laslett.*

3 July 1895.

"castle deck of the ship itself; it is pretty well "understood that this would take place, and from "my own experience shows me that it does take "place." You say in the same way he is mistaken in thinking that the Board of Trade Surveyors express the opinion that the lights ought to be amidships?—Yes; but the case of steamships and sailing ships is very different. As a matter of fact, very few sailing ships carry them amidships, they carry them forward, as pointed out here, for the purpose of being clear of the sails. It is the practice occasionally to have temporary fittings aft for bad weather. We have no power to object to that; but even then they will not show the 4° angle free of obstruction; but then it is only done in very bad weather. We do not recognise it, but we have no power to stop it; but the almost invariable practice of sailing ships is to carry the lights forward, a few on the forecastle head, but the great bulk of them abreast of the forerigging.

4629. (*Mr. Ismay.*) Do not some of the smaller ships carry their lights further aft?—Small sailing ships?

4630. Yes; schooners?—Yes; in the case of small coasting schooners you will find them sometimes a bit further aft; but I think you will find 9 out of 10 are forward.

4631. (*Chairman.*) Perhaps as you had experience before 1892 you can tell me what the practice was as to screening, so far as it came under your observation before 1892?—The object was to put the screen itself in a fore and aft line by measuring it across from side to side, and plumbing down the middle line, so as to get them equally distant, the side light then being placed on the lug outside the screen. To obtain the size of the chock, a measurement was taken from the outside of the screen to the inside of the lens, and that was carried forward to the fore end of the chock, and that gave it the thickness. It was the invariable practice; that always gave a convergence, but it did not give an uniform convergence, it was more or less in accordance with the size of the lantern itself and the length of the screen, but it always converged. In the Instructions to Surveyors, issued in September 1868, at the top of page 4, the several ways of regulating the convergence are given, and they agree precisely with the system carried out by the surveyors up to 1892 when the actual angle was defined. I carried out the same system as a shipbuilder before I joined the Board of Trade.

4632. Now, in point of fact, before 1892 what was the angle of screening contemplated by the Instructions of 1892—I mean in reference to the outer edge of the wick?—If the screen was 3 feet long before the lantern and the wick was shown on those sketches in the instructions, it would come to an angle of a little over 4° according to that sketch; but the angle itself really did vary from 3° to a little over 4°. The sizes and formation of the lamps is so immensely varied that there was at that time no real uniformity at all, but it was a very rare instance indeed where I should say the screening was less than 3°.

4633. So that, in point of fact, the effect of the 1892 rule was to increase the screening from 3° to 4°?—No, I say the minimum angle, which my experience would lead me to before 1892, was about 3°, but then we did not pay attention to the outside of the wick at all, but we went to the centre of the wick.

4634. I thought you said that you screened to the inner edge of the lens?—Yes, for the thickness of the chock, but the burner was outside the fore and aft line through the chock.

4635. What I wanted to know was, what angle that gave in practice from the outside of the wick?—It gave for a screen 3 feet long before the lanthorn a little over 4° generally.

4636. I want to compare the state of things before 1892 and the state of things after 1892?—I think that strictly carrying out the instruction as to a 3-foot length of screen before the light, with an ordinary 9-inch side-light, it made practically no variation whatever.

4637. So you think the practice before 1892, was substantially the same as after 1892?—Yes, but you get side-lights 9 inches on the side, and 10 inches and 11 inches; they will not give the same angle, but I am now confining my reply to a 9-inch side-light, and I think that the present 4° angle is practically the same as what it was before 1892.

4638. But you can test by your own experience in one way easily enough. Have you in many cases ordered the chock to be cut down?—I think I can say positively that in more cases we have had to put pieces on the chock than to take pieces off.

4639. Have you had experience of both?—Yes, I think I have made returns which show what the proportion was. I know over 50 per cent. were converged to 4° and upwards. I think, if my memory serves me right, that 56 per cent. of the lights we measured were screened 4° and upwards.

4640. A summary of your report has, I think, been already handed in*?—(*Produced and handed to the witness.*) Yes.

4641. "Of 369 vessels inspected, 115, or 31·2 per cent. were over 4°; 90 or 24·4 were 4°; 161 or 43·6 were under 4°. *Result* more than 55 per cent. were screened to 4° or over"?—Yes.

4642. That represents it?—That represents the facts of measurements.

4643. So that 55 per cent. were screened to 4° or over?—Yes, and I think I might say this, that we might have pressed our search in such a way as to increase that per-centage considerably. As a matter of fact we left out small vessels to a very considerable extent. They were all a large type of vessels. In small vessels the screens are apt to get bent and altered.

4644. I see there is a supplemental list at page 21. Is that also something for which you are responsible?—Yes.

4645. "List of vessels reported by the Board of Trade "by surveyors of the Liverpool and London districts, "showing the angle at which their side lights are "screened"?—Yes, I am responsible for that list.

4646. What is the date? When was that list made?—The 26th January 1893.

4647. That is to say, since the issue of the new rule?—Yes. I was instructed to take whatever assistance I needed, and go through the whole district, and report to the very utmost. I took two very experienced men, Captain Jeffrey and Captain Franks.

4648. And were all these lights which had not been altered since the 1892 rule came into force?—Your list would represent the state of things that existed before the new rule?—Oh, yes, before any of them were altered.

4649. Do you happen to know whether any of these were vessels which you yourself passed before 1892, and approved as satisfying the rule as to the inner edge of the lens?—I cannot say. My work is very varied, and I cannot recollect now.

4650. As to foreign ships, what is your experience of their screening?—Foreign steamers, or sailing vessels English built and owned by foreigners, have had the same screening, as far as I have been able to notice, as British ships. Most of those vessels have been built in England; and where they are not built in England they have followed out the English rules; but in regard to old wooden, Norwegian, Sweden, Danish, and Italian vessels, the screening has simply been anyhow. There has been no system in it. Almost invariably the screens are on the rigging, and they have no chocks at all, none whatever. The consequence is that the convergence is very much greater than in any English vessel that you can find. I do not mean to say that there are no exceptions; but I think I may say that at least 9 out of 10 old wooden Norwegian, or Swedish, or Italian, or Danish vessels, converge their lights to greater angle than British vessels; but all those vessels that have been passed over from the British flag to foreigners are put right before they pass.

4651. So that they follow the rule which for the time being was in force here?—Yes.

4652. That would apply, I suppose, to all the better class of steamers?—That would apply to all the better class of steamers.

4653. How do you actually take the measurement for the 4° angle?—We put a tape line across the ship, between the two sides of the screen, plumb down to the middle line—the centre of the ship—or we put a chalk line from mast to mast, or from the mast to the funnel, or anything that we can get in the fore and aft line. But it very often happens that we cannot get a fore and

* *See* Appendix 2, No. 2.

aft line at all—there are so many obstructions in the way—a pole compass, or a house or something of that sort. We try to get the fore and aft centre line in every conceivable way. Having got this centre line we take the distances from it at the fore end of the screen to its inside and at the position of the burner also. To the former we add the thickness of screen and chock, to the latter add thickness of screen and distance out from it to the outer edge of burner. The difference between these two sums is the convergence in the length of the screen. The angle this gives is obtained thus: Dividing the convergence by the length of screen we have the tangent of the angle from which we get the actual angle by reference to trigonometrical tables.

4654. (*Rear Admiral Andoe.*) We have it in evidence in several cases that there is a divergence, or rather a difference. in the screening of ships varying 5° or 6° perhaps; that is to say from 1° or 2° to 7° or 8°. I understand you to say that that is principally due to the size of the lamps, or rather to the fact that the position of the wick varies in its distance from the screen, or from the inner side of the lamp; is that the case?—I am afraid I did not make myself clear there. We have found in practice a very large range of angular convergence in actual measurements; the very first one upon this list is the "Achievement" which is 5¼ on one side and 7¼ on the other. What I meant was this, that if you put an 11 inch side-light in the same screen as a 9-inch lamp the angle would be much greater. That we find in practice; and it is a common thing in ships to carry two or even three sets of lights, and they vary in size and in the position they are in, so that the only thing we can do is to try it with all the lamps, but we have to accept one as the working set and it is upon that set that we base the 4° convergence. Whatever system you adopt—you will pardon me for saying so—unless it is in some manner arranged that every lamp that is carried shall converge to the angle you wish, it will never be done uniformly. For instance, I can mention the case of the "Argus" which was run into a short time ago and sunk. I visited her before she was towed to Glasgow for repair and she had two pairs of dioptric lens side-lights, and very fine lights they were, but one was 9 inches and the other one 11 inches, consequently the angle must have varied considerably.

4655. And consequently unless they are uniform sizes for all lamps and lanterns, whatever rule may be made for screening side-lights it will be of no use unless all the lamps correspond?—You might possibly regulate it by the lug at the back, keeping the 11 inch light nearer in-board.

4656. But that would not be practicable?—Yes, I think it could be done. It would require care; it would require a different kind of lampmakers to those that you have in existence now, because every tinker up a back street can make a lamp.

4657. But even then the man putting the lamp in position might make a mistake?—I mean this. Supposing that is a 11 inch side-light and you compare it with the 9-inch. The bracket on the 11 inch side-light would be about 2 inches further out than on the 9-inch side light.

4658. Do you consider that each class of ships should carry one type of side light?—It seemed to me to be impracticable to insist upon one defined size and one deemed type.

4659. Yet the whole of the divergence in the screening of the lights, appears to rest at the present moment upon the size of the lamp?—No.

4660. Because if you fix your screen for one particular lamp, and they put a different description of lamp aboard, we will say, and put it in the screen, the light will cross the bow at a different angle, will it not?—Just so. It would.

4661. Therefore the principle of screening from the inside the lens is not sufficient to regulate the angle altogether, because the distance from the inner edge of the lens to the wick itself, may vary in every lamp?—May vary in every lamp. That is quite true.

4662. And consequently the angle may vary?—Yes.

4663. At present we have not that?—No.

4664. How often do surveyors inspect the screening of lamps and ships after they have once been passed, do you think, to rectify any fault?—Well, I will say that it is the duty of the surveyors to visit vessels to the [illegible]

4665. What does that mean?—It means that if a vessel is away, say, several months, and there is nothing interferes, she can be certainly visited almost every voyage.

4666. And is it the practice of the surveyors to thoroughly measure and check the screens, to see that they are properly set as regards the angles?—Every time.

4667. Every time they visit them?—No, I should not say so.

4668. Then what is the object of their visit as regards side-lights?—The object of their visit is to take the accounts they have had on the previous occasions, and compare them, and see whether there is any alteration.

4669. How can the surveyor compare if he does not measure?—He sees the side-lights. He does not measure the screening every visit; but then you could not make much alteration in the screen without its being detected.

4670. Is it noted in the surveyor's book, the size of the chock?—Yes, the size of the chock is noted in the surveyor's book.

4671. Is that checked every time the surveyor goes on board?—I know I have seen it done many dozens of times. I cannot say that we do it every time.

4672. Because we have it in evidence that captains sometimes alter their chocks unknown to the surveyors?—Yes, I know that, and sometimes they get found out. The surveyors do not always make a report of small matters.

4673. Have you a copy of your surveyor's book?—Which surveyor's book?

4674. The book in which you make the notes when you pass a ship?—That is the kind of book we always carry; that is a new note-book (*produced*).

4675. But you have a printed form, have you not?—The printed form I was speaking of is filled up when the vessel was built.

4676. In that book you have certain questions and answers with regard to side-lights?—Yes.

4677. Have you got that here?—No, I have not got it here.

(*Rear-Admiral Andoe.*) Might we have one of those produced, Mr. Chairman?

4678. (*Chairman.*) Oh, certainly; this is only a note-book?—Yes, this is a note-book we carry round with us on all occasions.

4679. In which you write anything about the ship?—Yes.

4680. (*Rear-Admiral Andoe.*) With regard to the previous angle of screening; did you find that the largest and finest steamers that sailed from Liverpool were screened to the extent of 4° from the outer edge of the wick when they were examined in 1892?—In some instances they were not.

4681. Not at such a coarse angle?—Not at such a coarse angle.

4682. Were there many instances of that class of ship?—Well, I can only speak with regard to the largest class of ship from my knowledge of what my colleagues have done. I know from their reports that a large number of the highest class of ships had their screens converged to a fine angle.

4683. Finer than 4°?—Finer than 4°.

4684. Do you mean that those that were screened to 4° were rather a smaller and inferior class of ship?—Oh, no. I may say that in the course of my investigations they were more particularly carried on with regard to cargo vessels. Passenger vessels, of course, are specially appropriated to an individual surveyor, and he visits them every survey, the same man, from year to year. Therefore, my reports I think in every instance I may say, have always been in non-passenger vessels, but still very high-class vessels: for instance, Leyland's and some of the City vessels, and some of the Clan vessels—cargo vessels.

4685. And those vessels are 5,000 tons, I suppose, some of them?—Yes. The angle of screening varies considerably.

4686. Some more and some less than 4°?—Some more and some less than 4°.

*Mr. W. H. Laslett.*

3 July 1895.

4687. (*Mr. Ismay.*) You referred just now to the transfer of British ships to foreign flags; have you had much of that going on at Liverpool?—Not a very great deal. There have been vessels transferred to foreign flags, but not to a very great extent that I am aware of.

4688. Are they chiefly sail or steam?—Well, I think there are considerably more sailing vessels go over to foreign flags than steamers—mostly wooden vessels.

4689. There are some iron ships too, I suppose?—There are some iron ships.

4690. Do you in any way survey them before they leave?—The survey of British ships transferred to foreign flags depends upon the Government to which they go. In the case of the Norwegian and Swedish Governments, they authorise their consuls to transfer vessels of 100 Lloyds or 100 A1., and the highest class of Veritas without a survey; but all vessels under 100 A1. and 33–11 L. of Veritas go into graving dock and are surveyed by us previously to transfer, whether they are sailing ships or steamers.

4691. Under what Act of Parliament do you do that?—I am not sure whether there is any Act of Parliament authority for it unless it be the Act of 1876. I do not think there is any Act; it is an international arrangement.

4692. Then in dealing with these vessels as regards side-lights you would see that they are all screened to the 4° angle before they are transferred?—Yes, in every instance.

4693. I suppose you have formed some opinion about the position of the side-lights in these ships?—I have formed certain opinions as a ship builder. My opinions are founded mainly upon the experience which I have gained in the Board of Trade and as a ship builder, and from my knowledge that there are certain safe places and certain unsafe places.

4694. In your opinion what would be the safest place for side-lights to be placed, supposing you had the power?—I should like to see all side-lights placed so that they could always be under the observation of the officer of the watch, and as high up as they could be reasonably carried.

4695. And with what reference to the masthead light?—I think, as far as that is concerned, as the great bulk of vessels, or a large proportion of vessels, carry their side-lights considerably abaft the masthead light, it must have been found in sea experience to be the best arrangement.

4696. Is not the tendency just now rather to put them into towers at the end of the forcastle deck?—I do not know of any tendency of that kind; I have never favoured it myself.

4697. But still, there are ships so fitted?—Oh, yes, I know there are ships so fitted, but I am certain of this: that a surveyor has no authority whatever even to bring pressure to bear upon them providing they fulfil other conditions.

4698. I am not finding fault, but as you have had a very large experience with regard to side-lights (I should think almost an unique experience), I am anxious to know what you think would be the best place?—Personally I should always prefer to see in steamers at sea the side-lights abreast the bridge and as high up as you can get them.

4699. And abaft the masthead light?—Yes.

4700. (*Captain Hallett.*) You were talking of the spare lights. Do you insist upon vessels carrying spare side-lights?—We have no authority to do anything of the kind.

4701. When you find them with spare lights do you test the lights in their places?—Yes.

4702. And if they do not agree with standing lights?—We cannot stop their use. We can and do point it out to the master.

4703. But you have no power to do anything?—We have no power to interfere.

4704. Have you any experience of these big triple wick lamps, have you seen any fitted?—Only very few.

4705. On gimbals?—Very few indeed, exceedingly few. I have seen them in a few cases inside of lighthouses.

4706. Hung on gimbals?—Yes.

4707. Can you tell me whether those vessels had any spare lamps?—Yes.

4708. Of the same pattern?—The same pattern, yes. I think there are one or two of those in that list in the same way. They were Glasgow ships that had them.

4709. (*Mr. Bolam.*) Would you kindly tell us how we can tell when a ship's side-lights were surveyed and the angle determined; in past time I mean?—We have to ascertain first of all her movements, where she was last.

4710. You did not quite hear what I was saying. I want to find out when the "Ardnamult's" lights were screened; what date, what place, and what the angle of screening was. How can I find it out from official documents?—Well, your quickest way to do it would be to write to the principal officer of the district where she hails from, and he would fathom it out.

4711. How would he fathom it out?—He would say the "Ardnamult" runs between certain ports, for instance, she runs to Liverpool, her screens must have been seen either at Liverpool or at Waterford, or the port she belongs to. At one port or the other the information could have been obtained.

4712. Then you could have obtained the information about the "Ardnamult"?—Yes.

4713. Which you have not done?—I do not say that.

4714. But I thought you referred to the "Ardnamult" as the first ship you mentioned?—No, I have not spoken about the "Ardnamult" before. It was the "Achievement" I mentioned.

4715. Then you do not know about the "Ardnamult's lights?—Oh, yes.

4716. Would you kindly put in definite information as to where and when her lights were screened previous to 1892, and what the angle of screening was; I mean the same "Ardnamult" that is in the Board of Trade list; there is no port of registry, and no official number, so I must leave you to say which it is?—87,081; she has iron screens on davits at the fore end of the bridge.

4717. But if you would simply kindly give me the last date and place previous to the 4° instruction being issued where she was examined, and the angle at which the outside of the wick crossed the chock?—The angle was $3\frac{1}{2}°$.

4718. And the place?—And the place was Liverpool.

4719. And the date?—The 1st February 1893.

4720. But is not that after the 4° instruction was issued?—Yes.

4721. Can you give me the date preceding that, and also preceding the date of the 4° instruction at which the same vessel's lights were examined, and what the angle was at which the outside of the wick was screened?—I cannot tell you that.

4722. Can that information be obtained?—It could be obtained at the port where she was built.

4723. For instance, you see all you can determine from this is, that on the 1st February 1893 you examined the vessel's side-lights at Liverpool, and found that they were screened to $3\frac{1}{2}°$?—Yes, that is it.

4724. You do not tell us that the vessel's light screens had not been altered before coming into your hands, and after the issue of the 4° instruction?—No, I cannot say that.

4725. In the instructions to surveyors of 1894 the words occur, "Upon visiting a vessel for the purpose "of inspecting her lights and fog signals, the sur-"veyor should first inquire of the master for the "certificate of inspection." Then follows what the surveyor is to do in the way of comparing the lamps, and so on, if necessary. What is that certificate of inspection?—Every ship should upon being first built and registered receive from the surveyor through the builder a certificate for the side-lights giving the full particulars. It is issued on paper fcap. size, full of particulars. It is called Form Surveys 69.

4726. An official document?—An official document. I may say I find in practice that the owners rarely get that document.

4727. Why?—I cannot say.

4728. But who issues this certificate?—The certificate is issued by the surveyor, but he issues it to the

builder. You see the surveyor does not recognise the owner in the matter at all. He gets his application from the builder. The builder should hand over this document.

4729. Because you see the "Ardnamult" is one of the vessels which Captain Wade declares was screened so that the outer edge of the wick was screened to the outer edge of the chock; and the surveyor at Liverpool finds it screened to 3½°, and it would be interesting to see if Captain Wade had the slightest foundation for his statement. You have your survey, and I would like to know whether Captain Wade had any foundation for his statement?—He had not the slightest foundation.

4730. You only say that. But do not you see your evidence is only negative; and it is perhaps rather hard on Captain Wade in his absence to say there is not the slightest foundation for his statement?—The surveyor reported that he *found* the screen converged to 3½ per cent. on his visit on the 1st February 1893. He did not converge them to this angle, they were so before his visit.

4731. But in fact that certificate of inspection was issued when the ship was first built, and issued through the builder?—Yes, and it is very seldom that the owners have it. I do not know how it is.

4732. Captain Wade has declared that the angle of screening of the "Creaden" at the present time is 8° from the outside of the wick?—Yes.

4733. Your evidence about the "Creaden," if I heard it accurately, is that the screen is an inch out of the vertical line. It has $\frac{3}{16}$ths of an inch play?—$\frac{3}{16}$ths.

4734. And that the lamp itself has half an inch play?—Yes.

4735. If you happened to inspect the "Creaden" with all these faults at one end of their limit, and Captain Wade happened to inspect them when at the opposite extreme of their limit, the difference sideways may be about 2 inches; therefore he may have got his extra 4° in that way. If you add the $\frac{3}{16}$ths to the ½ inch, and to the inch, which will give you the maximum possible displacement between the two limits of the wobbling, you will see that Captain Wade would get something like the extra 4°. It is possible the difference may have arisen in that way. The surveyor may have been inspecting the wobbling at one extremity, and Captain Wade may have inspected it at the other?—As a matter of fact the weight of the screens keep them outboard to a certain extent. The over-hang draws them out. Then, again, the over-hang draws out the screen itself. Then you have to account for the wobbling of the lights. Now, I said to the captain "put your light as you always carry it," and he lashed it as he pleased, and I measured it. I say that you cannot by any possibility measure lights accurately under such a system existing as they do. It is quite impossible.

4736. But at any rate it is quite possible that part of Captain Wade's large angle may have been honestly arrived at?—Oh, yes.

4737. Then you say the practice of the Board of Trade surveyors up to 1892 was uniform. You mean uniform to this extent, that they brought the inside of the lens fore and aft with the outside of the chock parallel to the middle line?—Yes.

4738. Sir Digby Murray and Mr. Samson have referred to the diagrams in the instructions of 1868?—Yes.

4739. Are these diagrams of 1868 merely diagrams, or are they drawings drawn to scale? There is a very considerable difference between the two things?—I believe they are drawn to scale, but even if they are not drawn to scale; they are illustrative diagrams.

4740. Yes, all diagrams are illustrative; but in 1868 it was a very common practice even with scientific men to have a diagram which was not to scale, whereas now-a-days, it is the rule with people even when they draw mere diagrams to draw to scale?—I believe I am correct in saying that these diagrams were drawn by an engineer surveyor in the chief surveyor's office in 1868.

4741-2. And, therefore, presumably drawn to scale?—Yes, but the length of the screen was in advance of the lantern in these diagrams.

4743. Then you think that the screens in that diagram drawn to scale were 36 inches in advance of the lantern?—Yes.

4744. Not of the wick?—No, of the lantern.

4745. Sir Digby Murray has handed in these diagrams here with a scale marked upon them, and the length of the screen ahead of the wick varies from 48 inches to 44 inches. *This* is the paper which Sir Digby Murray has handed in to us just recently. Will you kindly check whether I am right or not (*produced*)?—All the screens are one length. You see, this is to show the way the convergence is to be taken and *that* line is well within the inside of the wick, but as a matter of fact they are not to uniform scale in all their details, but I think what they are and were intended to show could not be mistaken.

4746. Is this an exact copy of the instructions issued, apart from the measures put upon it?—*That* is an exact copy of *these* I have in these instructions from 1863 onwards.

4747. And to the same size?—And to the same size.

4748. So that if *these* are drawn to scale the longest screens here must have been 48 inches ahead of the wick?—Yes, but these screens have been all made to include the chocks in Figs. 4, 6 and 7.

4749. So that if the surveyors trusted these as drawings to scale the screens would be a good deal longer than 36 inches?—They *are* very often found 50.

4750. Previous to 1892?—Yes.

4751. Is that a fact which the Committee may take for granted?—Yes.

4752. Mr. Samson said in answer to a question of mine that the screens *might* be longer than 36, but that they *would* not be found to be so as a fact. I do not remember his exact words, but I give the general sense of his answer?—I do not say that there is a large proportion of them, but we have upon occasions found them upwards of 5 feet.

4753. (*Sir E. Harland.*) Was that in a British ship?—Yes.

4754. A steamer or a sailing ship?—Both steamers and sailing ships I have found so.

4755. (*Mr. Bolam.*) Then in reference to the position of towers about which there seems to be some difference of opinion, the placing of the side-lights when forward. You say the Board of Trade have no power to order side-lights to be placed anywhere?—Providing they show properly.

4756. And that they do not insist upon the lights being placed forward ahead of the masthead light?—No.

4757. In the instructions issued previous to 1892 are the words that "the lights be placed as far forward as practicable"?—Yes.

4758. And then later on "towers should be as far "forward in the ship as practicable"?—Yes.

4759. Is it not likely that the Board of Trade surveyors should have taken that to mean that the towers should be placed as far forwards as they could possibly get them, and decline to give a certificate where it was not so?—I do not think so; I have not been able to ascertain a case of that sort, and I think the instructions of 1892, at the bottom of page 9, provides for overcoming all possible obstructions by increasing the height of the light, as also by extending it outboard on outriggers.

4760. In the Liverpool district you yourself made out the per-centage of vessels in which you have had to increase the angle as 43·6 per cent. of the entire district?—Yes.

4761. So that at any rate in the Liverpool district a very large number of the vessels you inspected had to have the angle increased?—Yes.

4762. So that there were 43·6 ships that had the angle increased for 31·2 that had the angle decreased?—Yes, of the vessels selected.

4763. Therefore, judging from that figure there is some excuse for the popular view that the Board of Trade have increased the angle?—No, that is an unjustifiable view. I think to judge with fairness you must include those that are at the 4° angle.

4764. I did not put my question that way. 31 vessels would have the angle lessened, and 43 would have the angle increased. Of course 24·4 would be let alone.

*Mr. W. H. Laslett.*

3 July 1895.

*Mr. W. H. Laslett.*

3 July 1895.

Therefore in your district there would appear to be reason for the popular view that the Board of Trade have increased the angle?—It is a case of the representation of the minority, but not fair, I think, to say of the angle has been increased for the majority of ships.

4765. (*Mr. Scrutton.*) How many surveyors are there in the Liverpool district who examine side-lights?—Every surveyor in the district?

4766. How many?—There are 15.

4767. How many vessels do you think a surveyor could examine in a day, to do thorough justice?—It depends to a great extent upon the difficulties he has to encounter. It might take him two hours to do one ship, and he might get over it in half-an-hour. I have been on board many ships, that I could not finish in two hours.

4768. What would you consider the average of a fair day's work for a surveyor?—It is an unsafe thing for a surveyor to go on board a ship and do nothing but look after her lights, because the next morning he may be brought up with some question about something else about the ship which he may be expected to answer. But if he had the lights alone——

4769. I do not want to occupy time. My question is this. You are acquainted with the work a surveyor has to do. He has to do certain duties, and he has to do duties as regards lights as well. What would you consider a fair day's work for a surveyor at Liverpool?—I should say he would be very busy if he were to do eight vessels.

4770. And he works from 10 to 4, does he not?—10 to 4 are the office hours.

4771. What holidays has a surveyor?—They have 28 days in the year.

4772. You have stated that you consider that a surveyor visited every ship almost every voyage?—No, I say that a vessel going long voyages, or a voyage of several months, should be visited every voyage, and so they are.

4773. But you made a statement, I have got it down here, "Certainly visited almost each voyage?"—Yes, I mean all sea-going vessels, not coasting vessels that are in and out once or twice a week.

4774. You state also that there are certain surveyors who are told off to passenger ships, and they visit them every voyage?—Yes. In the case of emigrant ships.

4775. That is once a year?—On renewal of yearly certificate.

4776. They do not visit them between?—Not unless in case of accident, or in case of any casualty.

4777-8. Is there any reason to think that vessels are visited once a year?—Oh yes, certainly, a passenger ship is always visited once a year.

4779. Not a passenger ship, but other ships?—I should say myself, in my experience, that there are very few ships that escape being seen several times a year.

4780. My report from my marine superintendent is that out of say nine vessels, they have only visited two?—They do not come to Liverpool, and I do not know anything about the London district.

4781. But is it your candid opinion that every vessel is visited once a year?—I think so. I know it is the case in Liverpool.

4782. With regard to this list that you published here. Within what period was this list prepared; was it all done within a twelvemonth?—My instructions were to survey the whole ports straight off.

4783. And you did it all within what time?—Some of those vessels had to be seen half a dozen times before we could finish them. Certainly they were done within a month.

4784. How many vessels did you do all together; I have here 142 on page 4; would that be right:—"Liverpool district 169 vessels inspected"?—Yes, that is it. I sent in that list.

4785. What would that represent in your view of the number of vessels that were in in port during that time? Would it be a third?—First of all it excludes all passenger ships; it excludes all small coasting vessels—probably it is about one third—yes, perhaps it is about one third.

4786. I see in one list of 142 that you gave that in 34 of them that is 24 per cent., 34 out of 142, the port light and the starboard light are angled at different degrees?—Yes, we do find that.

4787. Is there any reason to think that that is a fair representation?—It is an exact representation.

4788. Exact representation with regard to 142, but have you any reason to think that that is a fair representation of the bulk?—Converged to a different angle?

4789. Yes?—I find here in this list numerous vessels, the "Achievement," the "Hector," the "Ariadne."

4790. There is no occasion to occupy time; it is a simple question; out of 142 vessels, in 34 of them the lights are at different angles—that is 24 per cent. Have you reason to think that is a fair representation of the vessels that come into the port?—The entire vessels?

4791. Yes?—Oh, no, there is not that variation.

4792. Then upon that ground this is not a reliable table?—It is reliable as to the fact of the individual ships it refers to, but if you take these proportions and apply them to the whole of the merchant service it might be very misleading.

4793. (*Sir E. Harland.*) You are the Chief Surveyor in Liverpool?—Senior Surveyor.

4794. Of course, you have a considerable number under you? You have referred to the lights in lighthouses; have you, yourself, checked the screening of those lights in lighthouses?—Oh, yes, I have done the greater portion of that myself.

4795. Did you find that it was easier or more difficult to check the screening in lighthouse than in the ordinary exposed lights?—I found it much more difficult.

4796. What was the cause of the difficulty?—Sometimes the smallness of the lighthouses and the difficulty of getting inside them—the difficulty of tracing the exact position of the burner inside of the lighthouse. It had to be measured and then checked outside in order to make sure.

4797. Then the first difficulty was, in ascertaining the true position of the burner in the one light relatively to the other, and relatively to the centre line of the ship?—Yes.

4798. Then would you recommend it as probably much conducing to the facility and accuracy of such measurements that each of these lighthouses should have a hole?—A door?

4799. Yes, or a hole of 1½ inches or 2 inches on the other side, opposite to the other lighthouse, so as to enable you to measure through?—Yes, but many of them now are having doors.

4800. Are there any in existence now with doors?—Yes, some of them, but only a small proportion.

4801. When did they begin to put in these doors, recently?—Not in reference to any measurements, but they put the doors for the facility of getting in and out.

4802. Then, it has the result of giving facility for measurement?—Yes, it does.

4803. Then, quite independent of the matter of getting in and out of that door, you will observe many lighthouses are entered from below?—Yes.

4804. Then, purely with the idea of enabling the surveyor to measure accurately the position of the wick in the lamp, you would strongly advise there should be those openings, solely with that object?—No, not solely, but I would recommend it because it is much easier for the officer of the watch to examine the lights from the deck than it is to go underneath it.

4805. That is the matter of the light burning. Now with reference to the screening of the lights would you recommend it for that purpose, for the matter of checking the measurements?—Oh, yes, I should be very glad indeed to see it: it would be very much more satisfactory.

4806. Would you also recommend surveyors in future should use laths for measurement in place of tape lines. I merely mention this from a circumstance that you know of?—I know that the tapes are not to be absolutely relied upon; and I think if you use laths, or steel pipes, you would get a much more accurate measurement, and more satisfactory.

4807. Then you referred to the screen sometimes being taken for granted as being fore and aft of the ship, and the screens being put there by the builder in the first instance fore and aft. Are you inclined to accept that position as a permanent one. Do you think there is no chance of those screens being struck by a sea and considerably shifted or bent?—They do constantly.

4808. Are you aware of some of these screens being of iron and rivetted to the lighthouses?—They are generally iron in these lighthouses.

4809. Do you know there are some that have no stay to them, under the idea that their own strength would be sufficient to maintain a true fore and aft position?—I have not met with one without a stay.

4810. But you think it would be desirable to have them tested?—I have seen those screens bent in, even with stays.

4811. Is it your opinion that the screen itself should be the first thing that should be checked as to its fore and aft position?—Yes; really and truly I should like to see something done to avoid the chock altogether.

4812. Would you go in for the screen being at an angle altogether, and if it is iron, being stayed so as to avoid the chock?—Yes.

4813. So that if there was no chock and the owner or the captain chose to change the side lights how would you then proceed to adjust it?—The only way I know to adjust is to regulate it by the lug on the back, shifting the lug in and out.

4814. That is to say, having one pair of lamps with a lug in a certain position?—Yes.

4815. And then having another set of lamps of another size, and to have the lug in such a position that the centre of the wick would converge in the same way?—Yes.

4816. And are you an advocate to taking the measurements to the centre of the wick, or the outer edge, or the inner edge?—Well, I think all things considered it is better to take it to the outside edge.

4817. Do you think it would simplify it or not, if the lamp manufacturers had some standard to go by to the effect that certain sized lamps should have a certain distance from the inner edge of the lantern to the centre of the wick, or would you say to the outer edge of the wick, or the inner edge of the wick?—The maker of the lantern if he wants an efficient lantern must put the centre of the wick to form the centre of the circle of his lens and his reflector. That fixes it really and truly; he has not got any choice about the matter.

4818. That is with reference to the lens, but with reference to the distance from the light to the inner face of the lantern, which is a matter which comes in in regard to the screening, what do you say about that?—I think, seeing that burners vary in size, and in worth, the outer side of the burner is the better thing to go by but whether you could make it an uniform distance inside or not I very much doubt.

4819. Supposing that, as we find in experience, the larger the ship generally is the larger the lamps are that are used, would you be disposed to recommend for the future guidance of lampmakers and Board of Trade surveyors that there should be say, two, three, or four standard sizes of lamps recognised, and that in each of those standard sizes of lamps there should be a certain distance, say, from the centre of the wick to the inner edge of the lantern; then if a shipowner chose to have a second or third set of spare lamps the Board of Trade should make the stipulation that they must all be of the one size for that particular ship?—Well, I should like to see a regulation to that effect.

4820. So that in a ship, say, with one set of first-class lamps, or first-class sized lamps, that there should not be a possibility, in case anything happens to the first-class sized lamps, of the officer of the watch changing them, and keeping others of a different size with a different distance between the wick and the side of the lamp?—Yes, I think myself that that can be regulated.

4821. Do you think that that would be a desirable way of regulating it?—Yes, I do.

4822. Do you think, although an owner now has the option of taking as many duplicate sets as he likes, if he takes them, you would advise that the lights should be suitable for the purpose for which he takes them?—Suitable for the fixed fittings that exist in the ship.

4823. Then how many sizes would you recommend for lamps? I have only suggested three or four, but how many various sizes in your experience are there at present in use. Supposing you had a selection before you as to sizes, how would you class them?—Well, I think 9-inch side-lights are small enough; they are rather too small. On the other hand, 11 inch side-lights are very big, heavy, and costly. I think if you made 9 inches the minimum size, and 11 the maximum, that would do.

4824. What would you come to after that?—I would not have anything smaller than 9 inches.

4825. But would you require a small coasting cutter or smack to have 9-inch ones?—Yes, most decidedly; it is the rule, and has always been the rule.

4826. Are there any smaller than 9 inches in use?—No, never.

4827. Then is it the case that there are only two sizes used now?—No. The minimum is nine, but the maximum has no limit.

4828. But what is your experience of the maximum size?—I have seen a few 12 inches.

4829. What is the maximum?—Do you wish me to give an opinion as to whether there should be a maximum size?

4830. I am asking you first, in your experience, what do you consider is the maximum?—12 inches.

4831. And in your experience what is the minimum size?—The minimum size is 9 inches.

4832. Are there no river craft with less than 9 inches?—Not that I am aware of, unless they are unregistered.

4833. They do not come under the Board of Trade unless they are registered?—They do not come under the Board of Trade unless they are registered.

4834. Then you make out by that three sizes; then would you recommend that for each of these sizes there should be a standard distance from say the centre of the light to the inner edge of the lantern?—But you would have to have others as well.

4835. But with regard to this question first; I am merely keeping in view the fact that if you ship lamps of different dimensions in the same screen you would have different angles of screening?—Yes, I do not see how if you put that screen to show right past this light you can have an 11 or 12-inch light to converge to the same as a 9 inch. If you put that lantern up against the screen you cannot have a fixed screen for the same distance from the centre of the lantern.

4836. I am confining you at present to the case of a ship which has 12-inch lights on board; would you recommend that the spare lights, if they had any on board, should measure the same distance from the centre of the wick to the inner edge of the screen?—Is that all at 12 inches?

4837. I am still sticking to the 12 inches?—Yes, certainly, if it is practicable.

4838. So that in this ship the one set of lights should measure the same as the spare set of lights and the screening would be right?—Exactly.

4839. Then would you recommend the same sort of principle in the 11-inch?—Yes.

4840. And that whatever size lantern the owner takes in the first instance, all his spare lanterns should have the same measurement?—Yes, but what we find in experience is not that they carry two of 12 or two of 11, but that they carry one of 9 and one of 11, and one of 12.

4841. Then, supposing they carry one of 9 and one of 11, and one of 12, so long as in each of those sizes they had the same distance from the centre of the wick to the inner edge of the lantern that would do?—But that is impossible.

4842. That is for the lampmaker, is it not? What is the impossibility?—You see *this* lens has a greater curve.

4843. But are you aware that the curvature of the lens has nothing whatever to do with the light?—Yes, exactly so, but in that case in bringing the lens over *here* you have a long black space *there*.

*Mr. W. H. Laslett.*

3 July 1895.

4844. But assuming the wick is placed in the necessary position to show two points abaft the beam, you would be in favour of the lamp measuring the same from the centre of the wick to the inner edge?—Yes, certainly, that is a very desirable thing.

4845. I noticed that in your evidence you mentioned that you thought that measuring from the inner edge of the lens was the same as from the outer edge of the wick?—Oh no, I did not say that.

4846. That the inner edge of the lens, so far as screening was concerned was the same thing as the outer edge of the wick?—I could not say that.

4847. I merely put this question to you; are you aware that the inner edge of the lens varies so much in different lamps?—Yes, it does.

4848. As measured from the inner edge of the lantern?—Yes.

4849. (*Chairman.*) I am afraid I have misunderstood you, because I rather did understand that before 1892 the rule was to screen to the inner edge of the lens?—Yes, before 1892 the rule was to screen to the inner edge of the lens, but I did not say that it corresponded with the inner edge of the burner.

4850. Then I understand you also to say that in practice, speaking generally, before 1892, the angle of screening was about the same as it was afterwards?—Yes, that is so.

4851. Therefore screening to the inner edge of the lens must have given about the same result as screening 4° to the outer edge of the wick?—Yes, that is so, but then the wick is not 2½ inches, it is only an inch. Therefore the inner edge of the wick is an inch and a half from the inner edge of the lens.

4852. (*Sir E. Harland.*) My question was to ascertain from you whether prior to 1892 you did not treat the inner edge of the lens as the source from which the light came, and the point which must be taken into consideration when you are screening?—Yes, that is so.

4853. Are you aware—or have you since been made aware—that the inner edge of the lenses vary so very much in relation to the centre of the wick?—I know it varies a great deal.

4854. Are you aware that the inner edge of some of the lenses come much nearer to the edge of the lantern than other lenses?—Yes, but it does not vary so much as the position of the wick does.

4855. But did you prior to 1892 go by the inner edge of the lens rather than by the wick?—Yes, if *that* is a piece of brass *there*, *that* is the point we take (*describing on the plan*).

4856. Then if you take *that* piece of brass, are you aware that that line has practically nothing to do with the wick?—It leaves it outside of it.

4857. Does not it leave an immense distance outside of it?—Yes, it gives the convergence.

4858. Then if your object was screening the light in any case with regard to the lens, was not that a very irregular method of doing it?—It was a method which gave a variety of angles.

4859. (*Rear-Admiral Andoe.*) A copy has been handed in of a "Form of Report to Board of Trade, made by "officers testing ships' lights." Perhaps you recognise that certificate?—That is it.

4860. And the next page?—Yes.

4861. That is in use by the Board of Trade, is it?—The note-book called Surveys 64 contains, on page 20, questions similar to those you refer to; it has been slightly modified lately, but a similar one has always been in use.

4862. How long has it been in use?—A similar one has been in use as long as I can remember.

4863. It says here, "Is the light visible at a distance "of two miles on a dark night with a clear atmosphere?" What steps did the surveyors take to satisfy themselves upon that point, and to answer that?—Well, very little.

4864. Was it done in practice?—It has been done occasionally, but very rarely.

4865. Does that apply to the next question? "Does "the light show over more than 10 points from right-"ahead, and if so, how many points more?"—It was checked by measurements.

4866. The next question is: "Is the light shown a "uniform and unbroken light in colour and power over "10 points of the compass, namely, from right ahead "to two points abaft the beam?"—That is a matter of measurement.

4867. Is it?—Yes.

4868. "Uniform and unbroken light." That would be observation rather?—Well, that can only be ascertained by sighting it forward.

4869. Has it been the custom to check that by observation?—It has.

4870. In every case?—In every case.

4871. By placing lamps in position?—By placing lamps in position and sighting them right round.

4872. By night?—Not by night.

4873. How can you do it by day?—You can see by day that it is free of all possible obstructions. We have very few opportunities of doing it at night.

4874. (*Chairman.*) Do you understand the "uniform and unbroken light" to mean merely free from obstruction?—"Uniform and unbroken" means free from obstruction, and that the colour of the light is fairly uniform from right ahead throughout, and that it is not in blotches of various degrees of colour.

4875. Then you do not understand that to refer to the cutting off any part of the light by a screen or chock?—It refers to the range of light from where it is cut off by the screen to where it is cut off at two points abaft the beam; between these it should show a full and unbroken light free from all existing and possible obstructions; the lens being of uniform colour throughout. The fact is these lenses vary immensely; and very poor lenses are so badly coloured sometimes that they have to be rejected.

4876. (*Rear-Admiral Andoe.*) Then it may be understood that this first part of the report, namely, "Is the "light visible a distance of two miles on a dark night "with a clear atmosphere" is practically a dead letter?—It is practically a dead letter so far as this; that if the instructions in other respects are fulfilled, we take it that this is fulfilled also.

4877. But you do not take it by observation?—We have no means of doing it.

4878. (*Captain Hallett.*) May I ask what you mean by a 10 and a 9, and a 12-inch light?—I do not quite follow?—It is the width of the side of the lantern.

4879. It has nothing to do with the radius?—No, it refers to the width of the lanthorn's side.

*Capt. W. Barker.*

Captain Wilson Barker called and examined.

4880. (*Chairman.*) I think you have been kind enough to prepare a memorandum showing the result of certain experiments?*—Yes.

4881. Will you hand that in?—Yes; and a diagram. And *those* are photographs showing the lamps, and the photograph of the flame (*produced*).

* Appendix 11.

## Wednesday, 17th July 1895.

PRESENT:

THE RIGHT. HON. SIR FRANCIS H. JEUNE IN THE CHAIR.

Rear-Admiral ANDOE.
Captain WILSON BARKER.
Mr. BOLAM.
Captain CASTLE.
Captain HALLETT.
Sir EDWARD HARLAND.
Mr. ISMAY.

Mr. C. HIPWOOD, *Secretary.*

Sir DIGBY MURRAY recalled and examined.

*Sir D. Murray.*

17 July 1895.

4881*a*. (*Chairman.*) I think you wish to hand in some papers?—Yes. The first is a further list* of vessels, showing the angle to which their lights were screened when the new rule came into force. Each of the original reports is initialled by the surveyor who took the measurements, so if any measurement is at any time disputed we can always trace it and produce the surveyor who made it and reported it. I think there has been some slight inclination on the part of some of the witnesses to think that the Board of Trade surveyors do not always act with perfect *bona fides*. But it is quite evident from those lists that they do. The revelation to the Department as to the lack of uniformity in the screening of side-lights was most unwelcome, and the surveyors in making their report as to the way in which they were screened, were perfectly well aware that it did not tend to their advantage or to the advantage of their Department.

The next paper is a report from the Glasgow surveyors with reference to some statements that were made to this Committee by Mr. Harvie.† It is hardly worth while to print the whole of it, but if you will allow me, I will say shortly what it is. First of all, I may perhaps be permitted briefly to state that the Marine Department issue no private instructions of the character suggested. Any person can buy the instructions, and there are no private instructions whatever issued. The surveyors report that all they required of Mr. Harvie was that the burners should be so fixed as always to remain in the same position in the lamps. They found that the burners moved in the lamps, and therefore it was no use their screening, say to 4° from the outer edge of the wick, when the next moment the burner might be moved in some other direction. And all they required Mr. Harvie to do was to so fix the burners that they should not alter their position.

Then Mr. Harvie told you something about the experiments with the lenses for the electric light.‡ Subsequent to the experiments§ which were carried out by the Board of Trade at the instigation of the Russian Naval Attaché, the Admiralty carried out a series of experiments; Mr. Samson attended them, and I am informed that they practically agreed with our own results. In consequence of these experiments we obtained glasses of the necessary tint for the electric light, and at Admiral Wharton's request I furnished them to the Admiralty. The Admiralty also made some experiments as to the tint of slides for oil lamps; they were attended by one of our people, and we obtained glasses for the information of our surveyors that exactly correspond with the tints adopted by the Admiralty. There is a light green and a dark green, and any tint between the two we think may be accepted. In the same way there is a dark red and a light red. They exactly correspond with the sealed patterns of the Admiralty.

4882. (*Chairman.*) I think Mr. Harvie produced a bottle of some liquid which gave the right tint for the green slide?—It is very possible he may have used that in getting out the different tints for the glasses. The Committee can if they wish see a pair of slides which were sent to the Board of Trade by the Admiralty.

4883. There is Mr. Harvie's bottle (*produced*)?—Well, that, I fancy, corresponds with the lighter of the two greens, and the lighter of the two greens answers extremely well for oil lamps; but it does not answer for the electric light; it is too pale.

4884. (*Mr. Ismay.*) The light is too strong?—Yes, that is the reason why we have recommended a separate tint altogether for the electric light.

4885. (*Rear Admiral Andoe.*) The slide for electric light is a darker green—a bluer green?—Yes, and rather a different green. These slides I have here are supplied by Chance Brothers (*produced*).

4886. (*Captain Hallett.*) Are these for the electric light?—These are for the electric light.

4887. (*Mr. Ismay.*) All the same?—All the same; only put up in parcels of four for convenience sake to send to the surveyors.

4888. (*Chairman.*) These, of course, only profess to be for the oil lamps?—Yes. Mr. Harvie was very indignant with us because we would not pass the greens for the electric light also. There is a little animus about it.

4889. (*Mr. Ismay.*) Is there not a practical difficulty arises where you have a separate shade for the electric light and the spare lamp is an oil lamp?—I cannot answer the question because all we can deal with are the pair of lamps which are put in their places for the use of the ship.

4890. But when the electric light is fitted it is usual, I think, if not necessary, to carry spare oil lamps, so that in the event of the electric current being interfered with they could substitute the oil lamps?—Exactly, but the oil lamps would be complete in themselves.

4891. But supposing they were fitted into lamp boxes into which there were fixed shades for the electric light?—No, the oil lamps would be complete in themselves, slides and all.

4892. (*Rear-Admiral Andoe.*) But are not sometimes lamps put into the lighthouses?—

4893. (*Mr. Ismay.*) I think I am wrong, if I may explain. If they substitute the oil for the electric, it is quite another thing altogether?—Quite, but even the darker of the two greens if it is used with a powerful electric light looks almost white. I have handed in our report, but the Admiralty have a quite independent one; they carried on experiments of their own at which Mr. Samson was present.

4894. (*Sir E. Harland.*) May I ask whether the coloured glass which suits the oil would not at all suit the electric light?—No, it would not.

4895. Then if the electric light, by accident, or necessity, had to replace the oil in the same lantern, and with the same lens——?—It would show with a powerful electric light, dependent upon the candle-power, under some circumstances almost white. It was in consequence of the Russian Imperial Yacht having nearly come into collision owing to the effect of the electric light upon the lens that the Russian Naval Attaché was put into communication with me, and asked me to carry out experiments to see what the result would be. I attended them.

4896. (*Rear-Admiral Andoe.*) It was an arc light, was it not, which was used in the Russian Imperial Yacht?—I cannot tell you. I see that Mr. Harvie said so. Our experiments were carried out in one of Sir Donald Currie's ships.

4897. (*Sir E. Harland.*) With the incandescent lights?—Yes.

4898. (*Rear-Admiral Andoe.*) Supposing I am correct in saying that the towers in which the bow lights are put, have coloured screens to them, and are generally

† Questions 3666-8.
§ Appendix 13, No. 1.

*Sir B. Murray.*

17 July 1895.

fitted with electric lights, are frequently made so that they have the means of substituting the oil lamp for the electric light in them, have you never come across, or heard of any such fittings?—I never heard of the fittings being used for the two kinds of lights; but you must remember that I personally do not carry out any of this work. I am resident at the Board of Trade; the actual work is done by the surveyors; but as questions crop up they are referred to me.

4899. But you are sure to have heard if a question of that sort arose?—I have heard of no difficulty, but I have heard of this; I know that in some ships there have been as many as three sets of lights, and when they were examined prior to the re-screening every pair of lights was found screened to a different angle.

4900. I think Mr. Harvie contends (and he has fitted, it appears, a great number of electric lights in ships), that the objection to having separate shades to the electric light is that when they have to substitute the spare oil lamp, which is expressly fitted to go into the box, it would give a different result?—Well, all I can say is that I should think that would be a lesser evil than to have an electric light fitted in such a way with such a light green slide that it would under certain circumstances appear to have no colour at all, or next to no colour.

4901. In that case, if the electric light passed through a very light green lens it would give almost a white light, would it not?—Yes, but even the darkest of these two colours—that was the colour that we tried with the electric light (*produced*)—mentioned in our report, at certain distances and with certain candle-power showed almost white.

4902. Then in the other case, if you were to fit the electric light to a dark green which is suitable for it, and you were to substitute an oil lamp behind that, you would almost obscure the light?—Most undoubtedly the light would be decreased very seriously. I do not think the coloured slides for the electric light ought to be used for the oil lights, or the other way about.

4903. Then would it not be desirable in the regulations to set out clearly that in the case of a light being changed either a totally different lantern should be used or that the slide should be changed?—I think in practice it is always the case (I cannot speak positively to it), that where oil lamps are used they have their own colouring quite apart from the electric light.

(*Mr. Ismay.*) I think the class of ships that use the electric lights have the stand-by light quite independent and separate; very often in an entirely separate position.

(*Rear-Admiral Andoe.*) I will produce Mr. Harvie's pamphlet; it is a very important question to seamen—if they have such a dark shade that it would obscure the green light almost entirely.

4904. (*Sir E. Harland.*) Whilst the Secretary is looking for that, might I ask this question: You have a standard colour for the oil light?—Yes.

4905. You also have a standard green light for electric lights?—It is entirely separate; the four slides you were looking at correspond with the Board of Trade standard for the electric light.

4906. But is this a sufficiently dark colour (*referring to a slide produced*)?—Yes, it answered admirably; this colour represents, with an electric light behind it, the lightest of the two shades of green which are used for the oil lamps; but I am afraid that Rear-Admiral Andoe thinks that the Board of Trade have more power than they really have. We recommend these things, but I do not think we have any power to insist on them.

4907. (*Chairman.*) But I dare say Rear-Admiral Andoe's view is, and certainly it is mine, that the Board of Trade ought to have the power?—I think they ought.

4908. (*Rear-Admiral Andoe.*) I do not cast any reflections upon the Board of Trade at all?—No, I did not think you did, but we have not the statutory power.

4909. The question I ask is whether it would not be desirable that the Board of Trade should have the power to enforce the regulations, for the safety of ships at sea, as to fitting their side lights?—Yes, and I have been pressing over and over again upon every successive Assistant Secretary of the Marine Department of the Board of Trade that the Board of Trade should have a range for testing these lights and proper people appointed for conducting the experiments. The artillery officers have been very good recently, and given us every opportunity, but they cannot be always doing it. It sometimes interferes with their own work, and I think that if any real progress is to be made in the future, the Board of Trade ought to have a range on dry land in which these experiments might be carried out.

4910. Is there any reason why lamps, before being accepted by the owners, should not be stamped by a hall-mark, to show that the intensity of the light through the lens, &c., had been passed by the Board of Trade, supposing the necessary means were there; a photometer room, for instance, properly fitted?—That is what I have myself proposed several times, but it means money.

4911. Such, I mean, as is invariably done with the lamps in the Navy?—I think it is very desirable, but it means money; and you may readily understand how very difficult it is for the Board of Trade to get money when you find the sum of money granted to me for the experiments in 1891 was only 25*l.*

4912. The point is whether it would be desirable, if it were not a question of money?—I should say it is infinitely desirable that the Board of Trade should have a regular range, and that these experiments should be carried out, and that the lamps should be stamped; every different set of patterns ought to be stamped.

4913. (*Mr. Ismay.*) Is not that the case with chain cables for ships?—Yes, it is.

4914. And anchors?—Yes.

4915. Something on those lines?—Yes.

4916. I think if it is important for cables, it ought to be more important for lights?—I think it is very important.

4917. (*Mr. Bolam.*) Before you leave the question of a standard light, would you kindly say whether two standards would be sufficient, one for oil lamps and the other for electric lamps?—I think that is a question which would have to be gone into very fully, but what I propose is—and I drew up a scheme some time ago, which was never carried into effect—that the different lamp makers in the United Kingdom, or the principal ones, should be asked to meet in conference and draw up rules. I think if we were to establish a hard and fast rule which would interfere with a number of these manufacturers it might lead to trouble, but I think if the trade were taken into the confidence of the Government Department superintending the matter that the whole thing might be arranged.

4918. (*Chairman.*) Now we will come, if you please, to those statements in the evidence already given, upon which you think it right to make certain observations. I think you desire to refer to various questions and answers, and I think you prefer to refer to them rather as questions and answers in the evidence than as having reference to the persons by whom they were actually made?—I wish, so far as I can do so, to keep clear of personal remarks of every kind.

4919. In Questions 1087 and 1088, a statement is put into your mouth with regard to the recommendations made by the Washington Conference—I do not think it is necessary to quote them at length—you desire to say something about that, I think?—Simply this; as I had never read the protocols it was perfectly impossible for me to make any such statement. I should have had to draw entirely upon my own imagination if I had done so. The statement has been made by somebody else, hence the misapprehension. I was asked, as I think I state further on, to deal with the resolutions arrived at at Washington so far as they concerned the Marine Department, and I never read the protocols; it is rather a big book to wade through. I only read the resolutions that they arrived at.

4920. I think you may have said that you did not believe it to be the practice of the Board of Trade to screen to so big an angle as 5°. I think that was your opinion then?—I think it was my opinion, and I have no doubt that at Washington when they talked about half a point they talked roughly, they did not mean that it should be absolutely so many degrees. This reminds me that I must correct a slight mistake in my previous evidence as to the average angle of screening prior to 1892. I find that in consequence of a misapprehension upon my own part, the new regulation having been formulated by Mr. Samson and myself entirely independent of the old ones, it escaped my observation that the length of the screen is measured from a different place now to what it was in the past.

As soon as I saw Mr. Laslett's evidence with regard to this point,* I wrote to Mr. Ramsay, and he sent me two sets of measurements, one supposing the length of the screen to be 36 inches, and the other to be 42 inches, and the reason that he sent the longer measurement was that he had noticed that the length of the screen would be greater. He did not call my attention to it; if he had done so I should have seen it at once, but he merely stated that there were two sets of lengths. I have recalculated all the table which he has put in, and I find it reduces the angle of 4° 32′ to about 4° 2′. I do not know that it is material, but I think it right to mention it.

4921. (*Sir E. Harland.*) May those two lengths not represent identically the same length? May one length not be 3 feet in front of the lens, and the other, say, 3 feet from the centre of the wick, or something of that kind?—No, I regret to say it is not; and I take the whole blame upon myself. I ought to have noticed the two sets of measurements are entirely different. The measurement from the centre of the wick I marked down in pencil on the end of the sectional drawings you have on the table, and at present the measurement is 36 inches from the wick. The old measurement was on an average 40½ inches when measured from the same place as we now measure from.

4922. Then might not that arise from some instruction to some surveyors that the screens shall be 3 feet in length, and that the surveyor has, therefore, perhaps very naturally measured from the lens to the end of the screen, which would be the 3 feet?—No; I think that they perfectly understand how the measurement is to be taken at the present moment, and you can quite understand the difficulty of measuring from the fore part of the lanthorn, because unless you get a sectional drawing you do not know the length of the screen from the wick, and it is only by getting a careful sectional drawing of every single lamp that you can measure it.

4923. (*Mr. Bolam.*) The instructions are specific previous to 1892, "three feet forward from the front "of the lantern;" and that is intensified by the table produced, which gives the length from the centre of the lantern as never less than 3½ feet and coming up to 4½ feet. If we take the two extremes, therefore, that will cut the average of 4° 26′ in the table down from 4° to 3°—4° with the shortest length, and 3° with the longest?—That was merely for reference purposes. I had better explain why this table was drawn up. I had one case of a surveyor in Dundee who stood upon the quay a very short distance ahead of the ship, and because he could not see both lights that short distance ahead he had the screening altered till he could plainly see both lights. I spoke to Mr. Gray, who was then the Assistant Secretary, about it, and I gave instructions to Mr. Samson to draw up this table, so that the surveyors would be able to tell what the screening should be according to the different lengths of screens. That was done, therefore, merely for their information.

4924. (*Chairman.*) Then I think you desire to say something with regard to what was said by the witness I have referred to as to the "Lusitania"† ?—Well, I have nothing to say myself about it. Of course I know nothing about it, but Captain Wilson reported to me that one of his surveyors had informed him that no alteration had been made in the screening of the "Lusitania's" side lights, as they were found to be screened to an angle of 4°. I informed Mr. Anderson of this, and he denied it, and I consequently referred the matter back to Captain Wilson, and his enquiry tended to show that his previous statement was correct. The surveyor was Mr. Rowe, and, perhaps, the Committee may wish to hear what he has to say, as it would be only fair to him. I may say that he is a very careful surveyor, and I should be inclined to think that his report was correct.

4925. In the answer to Question 1092 there is a statement as to the decision of the Washington Conference and the way it affected the action of the Board of Trade; that the Board of Trade felt bound to move in accordance with this decision. Do you agree with that view?—No, I say it was only with reference to the alteration of the screening from the centre of the wick to the outer edge of the flame. There is a letter from the gentleman who was Assistant Secretary at that time.

* Question 1121. † Question 1172.

4926. This is a letter written by Mr. Swanston:— "Junior Athenæum Club, 116, Piccadilly, W., 13th "May, 1895. Dear Murray,—With reference to the "screening of side lights, when the Board received the "Washington Resolutions Sir G. Nares undertook to "deal with those affecting his own Department, and "I requested you to consider those affecting the "Marine Department. But you were not in any way "tied down by the Washington Resolutions as to either "the vertical divergence of the lights, or as to the "angle to which the lights were to be screened. Of "course, the Board of Trade could not supervise the "construction of all the lamps used in the Mercantile "Marine without further power and increased staff. "It was pointed out to the deputation that this would "be equally true of Lloyd's, and you inform me that "Mr. Martell called upon you with reference to this "proposal and practically agreed in your view. Very "truly yours—GEORGE J. SWANSTON" ?—Mr. Anderson proposed that Lloyd's should undertake it.

*Sir D. Murray.*
17 July 1895.

4927. Then question 1098 says, "What took "place at this Conference? — Sir Digby Murray "again told us that he felt compelled to go as high "as 4° because of the Washington Conference and "of his own experiments, and because it was about "the average of the practice in the past; but he then "admitted what we had all along contended for, that "4° might be too much in narrow waters, and said he "would not be opposed to having two different screen-"ings, one for narrow waters, and one for the open "sea, but that suggestion did not seem to any of the "deputation a practical one." What do you desire to say about that?—I was not in any way bound by the Washington resolution. I did not admit that 4° might be too much in narrow waters, but I did say that the regulations were regulations for preventing collisions at sea, and did not apply to rivers and other inland waters. Page 5 of Departmental Paper, No. 179*, indicates the position I have always taken up on this subject.

4928. Then in the answer to question 1099, it is said, "We pressed upon the Board of Trade the need there "was that the lamps themselves should be of correct "and uniform construction in every detail, without "which uniformity of screening was unavailing. We "told the Board that the lamps at present in use were "extremely irregular, many of them being thoroughly "bad in every way. Mr. Corry will speak as to the "construction of lamps, so I will not anticipate him. "The Board said it was impossible for them to under-"take the surveillance of the lamps themselves, they "had not sufficient staff for the purpose. I suggested "that they should invite Lloyd's Registry to undertake "it, as in the matter of testing chain cables and fixing "load lines." What do you say to that?—Neither my colleagues nor I said it was impossible for the Board to undertake the surveillance of the lamps themselves, because they had not sufficient staff for the purpose. What Mr. Swanston and I said was that it was not practicable without further statutory power, and without this the staff was insufficient for the purpose; and that this was equally true of Lloyd's. Mr. Martell, who subsequently called upon me on the subject, concurred. In fact, Lloyd's would require to increase their staff much more than we should.

4929. Then question 1105, "What is the result at "which you arrived on this point?—Well, from what "I have said, it appears that the Board of Trade ex-"periments and inquiries into this subject which led "to the new order, were undertaken in consequence of "the Washington Conference, and that, but for the "Conference recommending the excessive convergence "which it did, the new order would not have gone so "far as to require a degree of convergence now ad-"mitted by the Board to be a possible source of danger "in narrow waters"?—I am unable to concur in any way in that statement.

4930. Then I think there is something you desire to say, is there not, with regard to the evidence of Mr. John Corry as to lights on board of his ships?—Well, I know generally what Mr. Corry has to say. I have not seen any of the diagrams that he put in before the Committee, but what I wish to say is this; that I have not seen any of the lights on board of his ships to which he alludes, nor have they been reported on to me, and I have not ventured to ask our surveyors to visit one of his ships, for fear of conveying to Mr. Corry the

* *See* Appendix 2, No. 7.

*Sir D. Murray.*

17 July 1895.

impression that I mistrusted his statements, which would be entirely the reverse of the truth; but lamps constructed after the pattern of Mr. John Corry's must have been very rare prior to 1892, and if screened as he suggests would only form an angle of 1° 6′ 45″ from the outer edge of the wick supposing the wicks to be parallel to the chord of the arc and the latter to form an angle of 45°. I should like again to call the attention of the Committee to the measurements made by myself in London and Leith, and to those made by Mr. Ramsay in the Tyne district, which shew that the mean angle of screening of all the lamps measured would be a little over 4°.

4931. Questions 2143 and 2144 are: "Now, in the "daytime meeting ships may have an angle of 4° "with the fore and aft line of your ship and be nearly "ahead of you? Yes. What angle would you call "nearly ahead of you? I should certainly not call "4°; 4° certainly does not come on the boundary; 2° "might; it would depend upon how far you are off." I think you desire to make an observation with regard to that?—Well, I should like to quote in the first place something that was written by me long ago before the Washington Conference. "Article 15. If two ships under steam are meeting end on, so as to involve risk of collision, each "shall alter her course to starboard, so that each may "pass on the port side of the other. This article only "applies to cases where ships are meeting end on, or "nearly end on, in such a manner as to involve risk "of collision, and does not apply to two ships which "must if both keep on their respective courses pass "clear of each other. The only cases to which it does "apply are when each of the two ships is end on to the "other, in other words, to cases in which, by day each "ship sees the masts of the other in a line or "nearly in a line with her own, and by night to "cases in which each ship is in such a position as to "see both the side lights of the other. It does not "apply by day to cases in which a ship sees another "ahead crossing her own course, or by night to cases "where the red light of one ship is opposed to the "red light of the other, or where the green light of "one ship is opposed to the green light of the other, "or where a red light without a green light, or a "green light without a red light, is seen ahead, or "where both green and red lights are seen anywhere "but ahead." Then this is my own remark: "It is "clear, if two steamships are meeting end on, or "nearly end on, the readiest way for them to avoid "one another is either for both to starboard or for both "to port, and no objection, I think, can be taken to "the rule that both are to port. The only criticism "I have to make is on the explanatory paragraphs. I "think these have the fault of aiming at too exact "definition. The first paragraph is, in my opinion, "amply sufficient, and the two last should be struck "out." I am still of the opinion I expressed then; and now let me put two questions. A is a steamship steering due W.; B is a steamship 2° on A's starboard bow, and steering E. 2° S., *i.e.*, directly for A. Are these two ships meeting end on or nearly end on? Again: A is a steamship steering due W.; B is a steamship 4° on A's starboard bow, and steering E. 4° S. Are these two ships meeting end on or nearly end on? In my opinion, in both cases the answer should be in the affirmative, and both ships should port. Perhaps you will permit me to put in a diagram* which entirely illustrates that.

4932. You have said that either rule, that both vessels are to port or that both are to starboard, would equally ensure safety?—Yes, if when both lights are seen both were to port, or both were to starboard—except that the regulations say both shall port. I know that that has been very carefullly considered by different rule of the road committees for a very long time past, and before I had anything to do with it.

4933. I do not quite follow that point for a moment, because where the rule is both shall port, or both shall starboard—we will assume it ought to be both shall port—if you say both shall port when both lights are seen and that they shall not port unless both are seen, that would lead to safety, would it not, if we suppose that the two ships are screened in the same way?—Yes, I say the screening ought to be uniform, they ought to be screened exactly in the same way, or as near as practicable.

4934. Then, supposing these two vessels were screened the same, and at 2° of bearing each saw only the green of the other, it would be perfectly safe in that case that they should starboard?—No, in that case one would port and the other would probably starboard.

4935. Why?—Because one would see both side lights, and the other only the green; if both saw the two side lights of each other, they would both port.

4936. That depends, does it not, upon whether you say that 2° constitutes end on or nearly end on?—No doubt if you were to say that 4° was not end on, or nearly end on, then ships in these positions would be left without any regulations whatever.

4937. Of course they would be left to the general regulations that ships must do whatever is seamanlike to ensure their safety?—I do not think that is enough for the masters and commanders of the smaller class of ships, especially; regulations are not meant for the most intelligent masters afloat, but they are meant for the less intelligent, and unless you have a precise rule to guide them, I am afraid you will find a good deal of danger will arise.

4938. I do not think we need discuss it more now, but I want to get clearly your view on this point: Supposing a man saw lights on his starboard bow, and after watching them saw them steadily come on, not broadening at all, under those circumstances it would clearly be his duty to starboard (*describing*)?—It is very easy to say that, and we are repeatedly told that you have only to watch the bearing of a ship to know whether she is going to collide with you or not, and in the olden days—if you were to go back 30 years—it may have been possible to a certain extent, but in the present days, especially in the Channel, a master of a ship would have no opportunity to so carefully watch all these bearings—he has not time, he cannot do it. He has to act on the spur of the moment, and it is not only sighting one ship, but sighting several in the Channel, and when he sights several ships at once, how is he carefully to keep watch of the bearings of those ships? It is utterly impracticable.

4939. (*Rear-Admiral Andoe.*) You do not suggest at all that it should be optional for him to starboard or port? I understand you to say that when one ship sights both the lights of another ship, she should undoubtedly port, whatever the screening may be?—No, I do not go as far as that, because one ship might see the two side lights of another when she was abeam of her.

4940. I am speaking now within the limit of ahead or nearly ahead, that is what we are discussing. But you do not suggest for a moment that she would take any other action but port as long as she sees both lights ahead or nearly ahead?—Yes, that is what I say under the present regulations; if you are going to alter the regulations of course that is another matter.

4941. (*Chairman.*) Now, question 2036: "You know it "is said that there is a misprint in the paragraph of "the Board of Trade Instructions of 1875 which "directs screening from the inside of the inner edge of "the wick, a misprint of *wick* for *lens*; but as the "lamps were made, do you think there was any "material difference between the screenings from the "inner edge of the lens and the inner edge of the "wick?—I have been informed, I forget by whom, that "Sir Digby Murray said there was a misprint there, "but in all the diagrams and the instructions to "surveyors the two lines are practically identical (*i.e.*, "the line joining the inner edge of the wick and the "outer edge of the chock cuts the inner edge of "the lens) as far as the scale of the diagram will "admit. I believe that in some lamps, constructed "by careless or ignorant makers, the two lines would "not be at all identical, but in the best lamps they "are." Well, I have never seen such a lamp; there may be such a lamp, but in all my experience I have never come across one in which the inner edge of the wick and the inner edge of the lens were in the same line. I will put in the diagrams referred to. I would not allow the draughtsman even to copy it; the drawings taken from the old instructions; and the only thing different about it is that these red lines have been put in to show the angle from the centre of the wick. This is the original diagram (*produced*). It has been lithographed as correctly nearly as they could manage it, and that is a woodcut taken out of the old instructions and pasted on the paper.

* *See* Appendix 13, No. 8.

4942. These are the diagrams from the old instructions, with some red lines added, are they?—The red lines are the only alteration; they are only drawn so as to show the angle from the centre of the wick to the outer edge of the screen or chock, as the case may be.

4943. So that your point, I think, is that these do not show the inner edge of the lens in the same line as the inner edge of the wick?—But more than that, because you will will see that it says, "but in all the diagrams "and the instructions to surveyors the two lines are "practically identical, as far as the scale of the "diagram of measuring them will admit of." I have simply put in those lines to show it is very easy to measure, and therefore that statement is not quite accurate.

4944. As we are on this subject, there is a matter to which I should like to call your attention. Rear-Admiral Andoe has been kind enough to call my attention to one plate in the later instructions of 1894, figure 4, which may explain what the witness meant; where it would seem, as far as the drawing is concerned, that the inner edge of the wick does pretty nearly coincide with the inner edge of the lens.

4945. (*Sir E. Harland.*) It is very near in this diagram of one of Harvie's lamps?—That is an unusual size of lamp, but it was the only one of Harvie's I had, and I had the drawings made of it.

4946. (*Chairman.*) It is Plate III, figure 4.* Certainly it looks as if a line drawn from the inner edge of the wick comes to something very near——?—It does in this drawing. but these drawings were not intended to show anything of the kind—only to show how the lights were to be screened—that is to say, the angle; these particular drawings are not to scale at all.

4947. But it is very likely, is it not, that what the witness had in his mind were such diagrams roughly drawn?—Well, I cannot say about that. I will look at it again. You must remember that those drawings were not applicable to what took place prior to 1892. What we have been discussing and what the witness was alluding to is what took place prior to the year 1892.

4948. Upon that there is a question I should like to ask you. In the International Regulations, Article 3, sub-section *c*, are these words: "On the port side, a "red light, so constructed as to show an uniform and "unbroken light over an arc of the horizon of 10 "points of the compass." Does not that imply that the construction of the lamp itself should be such as to show "an uniform and unbroken light." You will observe it is contrasted with the fixing of the lamp afterwards, as it goes on, "so fixed as to throw the "light from right ahead to two points abaft the beam "on the port side." Does not that imply that the lamp should be so constructed as to show "an unbroken "light over an arc of the horizon of 10 points of the "compass"?—I think, undoubtedly, it may be argued so, but I know it has never been construed to mean that.

4949. Then would you follow me as far as this; if that be, as it seems to me, the undoubted meaning of these words as they stand that cannot be effected except by having the limitation of the light effected by the edge of the lens?—I do not think that could be done without a screen or a screen and a chock, because it says an uniform and unbroken light, and if the lamp itself acted as a screen, you would only see the light over 10 points of the compass, but the light would not be an uniform and unbroken light over 10 points of the compass.

4950. Why not? Supposing you had a lamp so constructed that a line drawn from the edge of the lens to the inner edge of the wick, and a line drawn from the edge of the wick to the other edge of the lens gave you an arc of 10 points, would that not be a lamp so constructed so as to show "an uniform and unbroken "light over an arc of the horizon of 10 points of the "compass"?—No, it would be impossible; because the commencement of the first point would only be an edge of light.

4951. I do not quite follow that?—The article speaks of an uniform and unbroken light.

4952. Supposing the forward edge of the lens cut a line drawn through the forward edge of the wick from the centre of the lamp and the after edge of the lens cut a line drawn through the after edge of the wick from the centre of the lamp, could you not then have a lamp so constructed as to show "an uniform "and unbroken light over an arc of the horizon of "10 points of the compass"?—Yes, but not from ahead of the ship.

4953. That is another question altogether. But would that not be a lamp so constructed as to show "an uni-"form and unbroken light over an arc of the horizon "of 10 points of the compass"?—That is more than 10 points.

4954–8. Assuming that the two lines drawn through the two edges of the wick and cutting the two edges of the lens form an angle of 10 points, would not the lamp then be a lamp so constructed as to show "an "uniform and unbroken light over an arc of the "horizon of 10 points of the compass"?—I should like to draw this first to scale before answering the question, because the diagram here is very considerably over 10 points, and it would make a difference, I think, if you came to draw it accurately to scale.

4959. Cannot you imagine that to be 10 points?—Yes, of course I can imagine it, but then the result would not be quite the same.

4960. I will tell you quite fairly that the next question I should venture to ask you would be: Supposing you say that what I put to you would not do, then I should like to ask you, how could you then construct a lamp so as to "snow an uniform and unbroken "light over an arc of the horizon of 10 points of the "compass." If the plan I have suggested will not do what would do?—I think you can get it by the screening here.

4961. No, I want the lamp, please, apart from the screening. Do you say it cannot be done?—I say that in my opinion it cannot be done.

4962. Then in your opinion it would be impossible to comply with this rule?—The construction you are asking me to put upon it is, I think, not right.

4963. I merely want to get your view about it, because the rule says, "On the port side, a red light, "so constructed as to show an uniform and unbroken "light over an arc of the horizon of 10 points of the compass." Can any interpretation be put upon that other than that which I have ventured to put upon it; namely, that the construction of the lamp should be such that it should "show an uniform and unbroken "light over an arc of the horizon of 10 points of the "compass"?—I should be inclined to say that in order to arrive at that, you would be obliged to have the lens extending over an arc of more than 10 points. That is to say, to show an *uniform* light; it will show *a* light.

4964. A *uniform* light is what we have got to deal with. Then you think a lamp could be made to fulfil the conditions of this order which says that it is to be constructed so as to show an uniform and unbroken light over an arc of the horizon of 10 points of the compass?—Yes, but then you must remember that if you were to do it in that way, it would cut a portion of the light off the outer edge.

4965. That is another thing altogether. That is not what I am asking you, but the fact remains, does it not, that a lamp so constructed, must be constructed so as to have the inner edge of the lens in a line with the inner edge of the wick?—I do not agree.

4966. If that would not do it, what would?—If you will let the secretary take down your question in black and white, I will give you an answer and a diagram to-morrow.*

4967. Very well, I will do that. I think you wish next to say something about the answer to Question 2038, which deals with distance at which lights can be seen in the Mediterranean and Red Sea?—It is very difficult for a man who is navigating a vessel at sea to tell the exact distance at which he sees the lights, and I think the statement of the distance at which the lights show in the Mediterranean and the Red Sea requires confirmation. Especially do we require to know what is the candle power of the lamp; we are not told that. Another point is that there is no time when the lights are so great an advantage to a navigator

* Appendix 2, No. 1.

* I understand the Chairman's question to be whether a side light can be so constructed as to show an uniform and unbroken light over an arc of the horizon of 10 points of the compass only. If I am to answer this unconditionally of the question in the following paper as to what is meant by the words "ahead and abaft the beam," my reply is that it is not possible to properly construct a lamp to show in the manner indicated. To have a properly constructed lamp the centre of the wick must be the centre of curvature of the lens, and as the flame is not a mere point, but has considerable breadth, it would be impossible to limit the arc of the horizon to 10 points of the compass only.

*Sir D. Murray.*

17 July 1895.

as when the weather is thick, and when the weather becomes thick on board these vessels burning electric lights I am informed that the candle power has to be reduced in order to diminish the reflection, which would otherwise be prejudicial to the navigation of the ship. The result of this is that the penetrating power of the light is diminished at the time when it is most wanted. It is also to be remembered that the regulations are regulations for preventing collisions, and do not apply to distances at which there is no danger of collision.

4968. In answer to Questions 2052, 2053, 2054, 2055, the witness gave instances of his experience with regard to steamers meeting one another—it is not necessary to read them at length. What do you say to that?—I think, if it can be shown to what angle the lights were screened in all these vessels, there might be something in it, but the angle to which they were screened is purely an assumption, and under these circumstances I really cannot see what is the value of these instances.

4969. Now, Question 2065; the question and the answer are: I think it was pointed out to you, was it "not, by the officials of the Board of Trade, that some "statistics showed that 4° of convergence was about "the average of previous practice. What would you "say to that suggestion?—Well, I got these statistics, "and dissected them for myself, and I found, whether "by accident or design, that nearly all mail steamers "and vessels of the best class, which would have "powerful side lights, were left out of them. "They were nearly all either cargo steamers or sailing "vessels. In the Liverpool list there were four "Cunard steamers; they were the only ones that I "could see that were mail steamers at all. In the "London list there were a few more, but five of "those in the London list had their lights screened "parallel, and the others were from 1° to 3½°. The "whole of our fleet and the Pacific Company's fleet, "where the chocks had been pared away (I have "this on the authority of our Marine Superintendent "and Captain Conlan, Marine Superintendent of the "Pacific Company), there was nothing said about "them. There was nothing said about the P. and O. "ships, with a few exceptions in which the angle "was less than 4°, which were altered previous to "that measurement. I felt that they were altered "the wrong way according to my argument. They "were not altered to decrease the angle, they "were altered to increase it." And Question 2066, "In your opinion, were there whole fleets of steamers "of which yours was an example where the angle of "convergence was only about a degree?—Yes, I "did not measure them all: I know they were all "done on the same principle, and my own was a "degree, or a degree and a sixth exactly. I calculated "it to be accurate from the shadow thrown by the side "lights on the screen, the shadow of the chocks "on the screen; then when I actually measured the "crossing points with the lead line in port afterwards, "they agreed within 7 or 8 feet." I think you have looked at the list of vessels, have you not?—I have. I find that there are 37 vessels included in it, belonging to well-known companies, most of them having their lights screened to a very fine angle, or else to no angle; they are as follows:—

| Name of Companies. | No. of Ships. |
|---|---|
| Cunard Steam Ship Company | 5 |
| Peninsular and Oriental Steam Navigation Company. | 3 |
| Royal Mail Steam Packet Company | 3 |
| Donald Currie and Company | 3 |
| Union Steam Ship Company | 3 |
| J. and A. Allan | 1 |
| Dominion Steam Ship Company | 3 |
| Anchor Line | 1 |
| City Line | 1 |
| F. Leyland and Company | 3 |
| T. and J. Brocklebank | 1 |
| West India and Pacific | 1 |
| W. Johnstone and Company | 3 |
| Oceanic Steam Navigation Company | 2 |
| Telegraph Maintenance Company | 1 |
| British and North Atlantic Steam Ship Company | 2 |
| National Steam Ship Company | 1 |
| Total | 37 |

These large steamships form a minority of the mercantile marine fleet, and the wonder to my mind is not that so few of this class of vessels are recorded amongst the comparatively small number of vessels in the table, but that so many are recorded. These tables were not intended to show the average angle of screening, a far larger list would have been necessary for this purpose, but merely to indicate the lack of uniformity which, in the opinion of the Department, required a remedy. I have no doubt in my own mind that there are some ships of which we have obtained particulars which we have never printed. At one time we thought that all this agitation had died out, and the Department always has to avoid any unnecessary expense, and in consequence many of the lists were put on one side and not printed. All I want to show the Committee is that everything has been done perfectly fair and above board; the lists which have been printed are exactly as they came in; the reason why the later ones are not printed is because they came in after the others were printed; but I have one report here showing the manner in which the lights were screened at Greenock.

4970–3. Then question 2108: "And it was a very "extraordinary thing that when those statistics were "prepared by Sir Digby Murray there were hardly "any mail steamers in them. I think in the Liver"pool list there were four Cunarders and one was "1° another 1½°, another 2° or 3°, and another 2°, as "well as I remember?"—Well all I can say is that statistics of this character were never prepared by Sir Digby Murray; the particulars furnished by the Liverpool and London surveyors were printed in exactly the same condition as when received by the Department; they were not weeded out or picked in any way.

4974. Question 2239: "Is there any advantage at sea "at all, in point of fact, with a large angle of "screening?—None whatever. The man that carries "out the rules of the road so like an automaton as to "to rub sides with the fine screening will do the same "with the 4° angle, which has all the navigational dis"advantages I have enumerated. I have never heard "but one argument in its favour, and that was Sir "Digby Murray's own opinion: and he told us when "we went to see him in deputation that if two vessels "were approaching one another in foggy or hazy "weather, and that if they could not see both side"lights, there would be a risk of collision. Well, I say "if they got as close as that the side-lights will not "avoid collision. There is nothing but full speed "astern?"—Well, he does not say what the distance was. I remember perfectly well what I said at the time.—I said "at distances ranging from a quarter "to half a mile," That was about the distance probably in thick weather that they would be visible if they were visible at all.

4975. I think there was a paper* which you have been kind enough to prepare as to the general conclusion with regard to the screening of ship's lights; perhaps the best plan will be, unless you desire to add anything to it, to put that paper in as it stands?—Yes; I have a letter I should like to add to it. There is another paper with reference to the experiments. Then if you wish to have the paper put in as it stands, I should like to add a letter and a tabulated statement to it.

4976. Is there anything else you wish to say with regard to the paper of general conclusions?—I do not know that there is anything; I think it speaks for itself. The only thing I do feel very strongly upon is in the letter-press at the bottom. "It is necessary to "consider what is nearly right ahead before the "angle of screening is determined."

4977. Then there is the question of experiments. You know we have made certain experiments, and we should be very glad to hear whether you think there are any other experiments or any other conditions of experiments which ought to be tried?—I think that the experiments are not complete unless they are made under different atmospheric conditions. You have only to compare the experiments of 1893 with those made in 1895, which were carried out in the most careful manner, to see that a very great difference is caused by different states of the atmosphere. You will see that in the 1893 experiments the light from the outer edge of the flame and also the diffused light from the

* Appendix 13, No. 2.

lens was invisible at both the distances of 500 and 1,000 yards, so that all that was seen on that occasion, although there was only a low-lying haze, was the portion of the flame corresponding to the angle from the outer edge of the wick.

4978. There is another matter which I think you can clear up. We have heard a great deal about the "dark lane," a phrase which rightly or wrongly has been attributed to you. I think you intended by that to convey only what would arise if a light were screened to no degrees from the outer edge of the wick?—Yes, I think I would prefer to put it in the manner that many of our opponents have put it, and say that if the light was so screened that it did not cross the line of the keel projected ahead of the vessel, under those circumstances you must have a dark lane.

4979. But supposing it was screened to the inner edge of the wick, you do not under those circumstance suggest that there ever is a dark lane?—No, I do not, if you screen it from the inner edge of the wick; you will, however, have to be a considerable distance from the light, especially in thick or foggy weather before you will see the whole of the light, before you will see a uniform light.

4980. But you will see the light at such a distance as will render any such phrase as a "dark lane" inapplicable?—Yes.

4981. (*Mr. Ismay.*) Have you any objection to screening from the inner edge of the wick?—Yes, I have a very strong objection. In the first place, the screening, I think, ought to indicate the width of the field, and ought to be fixed in all cases. If you were to screen from the inner edge of the wick you would have to make the position of the wick in the lantern statutory; and then if you do that it does not matter whether you screen from the inner edge, or the centre, or the outer edge.

4982. But supposing you were screening parallel with the keel you might do away with the angle altogether?—I think the screening from the inner edge of the wick would be altogether too fine. As I pointed out, any surveyor may make a mistake of half a degree in screening a side light. You see, in the first place, our Board of Trade staff is limited, the surveyor has to perform his work at any time; raining or snowing or blowing, he has to carry it out. When the screens are on the top of an upper or flying bridge it is most difficult, especially in bad weather, to screen lamps to a nicety. There is generally only one surveyor at work, and he may not, and he does not, get in many cases sufficient assistance. He cannot be at both ends of the batten at the same time; and as I have pointed out in the paper I have put in, a mistake of only three-tenths of an inch will make an alteration of half a degree one way or the other, and of course, the finer you make the angle of screening the greater the error is in proportion. Half a degree is only one-eighth of 4°, while it is one-half of 1°, and if you screen from the inner edge of the wick that is in round numbers what the screening will be reduced to. I may point out that the Rule of the Road Committee, after the first night's experiments, gave up all idea of having a 1° angle, they would not test anything less than 2°.

4983. And you think in the experiments recently made the weather was rather too favourable, and rather too uniform?—I sincerely wished before you went down there that you might have one rainy day, so that you might see what an extreme difference a change in the atmospheric conditions would make.

4984. (*Rear-Admiral Andoe.*) When the last Committee—the Rule of the Road Committee—reported regarding the screening of side lights, they said, in the last paragraph: "At the same time we desire to "point out that no strict uniformity of the angle at "which the full strength of the lights is in practice "visible is possible so long as a great variety of "patterns of lamps are in use, and, in view of this "fact, as well as of the great improvements which have "been and are being made in the construction of "lamps and in the power of illuminants, and of the "great increase in the size and speed of ships, we "think that the Board of Trade should in certain cases, "upon the request of the shipowner, have power to "allow the angle of screening to be reduced to 3°, or "in special cases to even less than that angle." Can you properly say what reason the Board of Trade had for not carrying out that suggestion?—Because no application has been made. A report was printed, but the shipowners made no application. There is a paper, which I thought I had brought here with me, in which I at the time took down what took place at the Committee. I referred it to Mr. Hipwood, who was the secretary of the Committee, to ask whether it was correct.

4985. Was it intimated to the shipowners that this point would be given consideration?—No; but then the report was circulated publicly.

4986. What report, *this?*—Yes, the report of the Rule of the Road Committee, and the P. and O. had their marine superintendent on the Committee. It was well-known in the City.

4987. But it was never specially intimated to shipowners in any way?—No.

4988. (*Mr. Bolam.*) And no instructions were sent to surveyors to concede the angle?—No, because it was never intended that the surveyors should concede it. What took place was that it was agreed that if the shipowners wanted to screen their lights to a smaller angle than 4°, they should send those lights to be experimented upon, and if they were found in consequence of their great brilliancy to show to a greater angle than 4°, then the angle should be reduced until they showed to 4°; and a very difficult thing I should say it would be to do it, because the difference in the atmospheric conditions is so very very great that it is very difficult to arrive at any conclusion. I should like to say something with reference to the suggestion that there is any difficulty in regard to the broad screening. I should also like to refer to the regulations of the Thames Conservancy. I was asked by Lord Farrer, who was chairman of the Thames Traffic Committee, to draft these regulations for the consideration of that committee, and, so far as I can remember, they were adopted without change, and subsequently embodied in the byelaws of the Thames Conservators.

4989. (*Captain Wilson Barker.*) I notice Sir Digby Murray says in his General Conclusions on Screening Lights, that Mr. Samson and he thought at one time that the red light should be screened rather differently to the green?—That is so.

4990. And I see all these experiments show that the red light showed very much more over the bow, in fact, nearly twice as much as the green light?—So far as the mere question of lights is concerned, apart from the steering and sailing rules, we were of opinion that the red light might be very well screened at 3°, providing the green light was screened to 4°. Since that, however, I have seen many green lights which show quite as far as the red, but there are undoubtedly a good many green lights at the present moment which would not show for anything like the angle. The only reason we did not recommend it was that there was such a striking want of uniformity in what had taken place in the past, that we were afraid to have any difference.

4991. (*Mr. Bolam.*) Upon that may I ask whether you knew the candle-power of the lamps used in the experiments at Glengall?—No, I do not, but evidently, from the experiments, the green light must have been a very bad light. I was rather in error, perhaps, in stating it was a plano-convex lamp. I ought to have said it was a plano-convex light with a coloured lens but no slide. There is a photograph which perhaps I may be permitted to put in; it was asked for before, but I did not wish to put it in without explanation. Those flames all proceed from wicks of the same size, that is to say, 1-inch.

4992. (*Chairman.*) What was the difference of conditions?—The principal difference of conditions was the way in which they were trimmed—in this lamp the edges of the wick were cut off, and the wick was rounded. That is the reason why there is so small a flame, but a difference in the compression of the wick itself makes a most wonderful difference. I was so surprised at what took place during the experiments, that I had the lamps sent up as they were to our office in Bedford Street, and then I wrote to Captain Abney about it, and told him I was very anxious to have some accurate photographs, and he was good enough to have these photographs taken. You see they are signed by him.

## Thursday, 18th July 1895.

PRESENT:

THE RIGHT HON. SIR FRANCIS H. JEUNE IN THE CHAIR.

| | |
|---|---|
| Rear-Admiral ANDOE. | Sir EDWARD HARLAND. |
| Mr. BOLAM. | Mr. ISMAY. |
| Captain HALLETT. | Mr. SCRUTTON. |

Mr. C. HIPWOOD, *Secretary*.

Sir D. Murray. 18 July 1895.

Sir DIGBY MURRAY re-called and further examined.

4992*a*. (*Chairman.*) I think you wish to say something about the report of the Rule of the Road Committee not having been communicated to shipowners?—Yes. I told the Assistant Secretary what took place yesterday, and this is the statement he wishes me to hand in, "The report of the Rule of the Road Committee, "dated December the 8th, 1893. This report was "presented to Parliament and printed in the Parliamentary Paper C. 6869, but the attention of shipowners and others affected was not specially directed "to it. It is not usual to call attention to such "reports, and, in fact, it would be superfluous to do so. "They become public property by publication, and the "press, the societies, and the associations connected "with the various shipping interests ensure such reports being generally known and carefully criticised. "No application has been received from any shipowner "for a reduction below 4° of the angle of screening."

4993. (*Chairman.*) You were kind enough to refer to the Thames Rules in support of your view?—I am not aware I so much quoted them in support of my view except that I think the narrower the channel the safer a broad angle of screening is; for instance, if you take a mere ditch or a channel like the Clyde, surely a pilot knows whether he is on the side of that channel which lies on his own starboard side. In fact, so far as the ships proceeding up and down a narrow channel are concerned, I do not think it matters whether there are any side-lights at all.

4994. If you take the view that they ought to be guided by the local regulations, and not to be guided by lights, it does not matter whether there are side-lights at all?—No, but it is necessary in a river like the Thames that there should be side-lights, because there are a number of barges and small craft crossing backwards and forwards, and it is absolutely necessary that they should have side-lights screened in such a way as to afford the necessary information to ships passing up and down the channel or fairway.

4995. Then the instructions would be the same as instructions in open waters?—I do not see the slightest difficulty. I have read very carefully the evidence on the subject, and I do not see that there is any force in the contention that the 4° angle of screening is especially unsafe in narrow waters. There is not any danger, and I know a great number of people are of opinion that there is not the slightest danger; but what I want to draw attention to is the Thames Rules. Rule 22 is very much like Article 21 of the International Regulations. It says, "When two steam "vessels proceeding in opposite directions, the one "up and the other down the river, are approaching "one another, so as to involve risk of collision, they "shall pass one another port side to port side." Then this, I think, is the most important rule we have:—"Steam vessels navigating against the tide shall, "before rounding the following points, viz., Coalhouse "Point, Tilburyness, Broadness, Stoneness, Crayford-"ness, Cold Harbour Point, Jenningtree Point, Half-"way House Point or Crossness, Margaretness or "Tripcock Point, Bull Point or Gallionsness, Hook-"ness, and Blackwall Point, ease their engines, and "wait until any other vessels rounding the point with "the tide have passed clear." And I think that rule has done more to avoid collisions than any other. Then there is the further one:—"Steam vessels "crossing from one side of the river towards the other "side shall keep out of the way of vessels navigating "up and down the river."

4996. Those rules are all quite independent of any sidelights at all?—Quite. The regulations for sidelights are exactly the same as in the regulations for preventing collisions at sea. We found the rule for vessels rounding points work so well that we extended it to the upper river, and we are now going to modify it again so as to make it a little wider: "Steam vessels and "steam launches navigating against the stream above "Richmond lock shall ease and if necessary stop to "allow vessels coming down with the stream to pass "clear, particularly when rounding points or sharp "bends in the river." These rules were thoroughly considered by the Thames Traffic Committee, after I had drafted them at Lord Farrer's request. I have here the report of the Thames Traffic Committee, containing the rules as they recommended them.

4997. The rules seem to me to follow the report exactly?—Very much so. I do not know whether you wish me to leave this photograph. It is merely for the information of the Committee. I am not basing anything on it with the exception that I think it show that the trimming of the side-lights makes a considerable difference, and even the compression of the wick has a great deal to do with the width of the flame.

4998. (*Sir Edward Harland.*) What do you mean by compression?—Whether the wick is loosely wove or tightly wove.

4999. (*Chairman.*) If you will kindly leave these?—Certainly, with pleasure. I may say that these slides placed on the table were sent by the Admiralty to the Board of Trade on our application.

5000. (*Chairman.*) That is everything, I think, that you desire to say at the present moment?—There is only one thing more, which I did not say yesterday. I think I called your attention once before to the pamphlet on the regulations for preventing collisions at sea by Mr. Thomas Gray. I think some of the Committee have considered since that these are Board of Trade Rules, but they are not, except in so far as they have received the official approval of the Board of Trade, the Admiralty, the Trinity House, the French Government, and other nations, and that this approval has never been officially withdrawn. I have only read a part of what is on page 7, and I should like to draw your attention to these words: "6. Every one is "unanimous in agreeing that no two ships can come "into collision so long as they show each other the "same coloured light, green to green, or red to red. "7. The rule cannot therefore apply:—*a*. when a green "light is seen anywhere on the starboard side: *b*. "When a red light is seen anywhere on the port side: "*c*. Nor can it apply when a red or a green light is "seen ahead. 8. There is not the remotest chance of "collision in either of the cases above put. It would, "therefore, be idle to make rules to define what the "ships so situated are to do to prevent collision: and "yet the government have been asked to make such "rules." If the public wanted it at a time when there was no danger of collisions in this respect, because the lights were then so broadly screened, it would seem to me that if the angle is to be decreased there would be very considerable reason for providing them with such rules.

5001. It is the case, is it not, with vessels of great beam, something like 70 feet or so, even with a 4° angle of screening, that there would not be absolute perfect safety?—No; everything is comparative, and you could not make it absolutely safe at wide angles of

screening, but the more you decrease the angle the less safe you make it.

5002. May I ask this one question, *apropos* of something you said yesterday. You said: "I am still of the "above opinion, and now let me put two questions: "A. is a steamship steering due W. B. is a steamship "2° on A.'s starboard bow, and steering E. 2° S.—*i.e.*, "directly for A. Are these two ships meeting end on, "or nearly end on?" Again, "A. is a steamship "steering due W. B. is a steamship 4° on A.'s star-"board bow, and steering E. 4° S. Are these two "ships meeting end on, or nearly end on? In my "opinion the answer should be in the affirmative, and "both ships should port." Will you allow me to add a third question: A. is a steamship steering due W. B. is a steamship 5° on a starboard bow, and steering E. by 5° S. Are those two steamships meeting end on, or nearly end on?—Well, that depends upon the consideration which I have stated here, the absolute necessity of determining what is nearly end on.

5003. But you have not answered my question. Your answer as to 4° is that it should be given in the affirmative, and both ships should port. What do you say as to 5°?—I think, as I have already said in the paper, that I should like to make it 4½°.

5004. Then would you say that at 5° he need not port?—At 5° it would not apply, provided that you decide that nearly end on is limited to 4½°. If you said, for instance, these vessels were nearly end on when they were 4½° on each other's bows, and approaching with risk of collision, then of course it would not apply at 5°; but in practice I think you will find that on board a ship it is very difficult to determine the exact number of degrees.

5005. Then you see where that lands you if that be so. You say that the answer should be in the affirmative as to the 4°, but you will not give me the same answer at 5°?—Well I think it would be infinitely safer for them both to port at 5°.

5006. Then I will go a step further, and say 5½°?—There must be a limit somewhere, and I can hardly point out to you the dividing line.

5007. Do what you will, there must be some point at which that vessel must see the two lights of the other approaching towards her, she herself exhibiting only one light?—Yes, certainly.

5008. Therefore, so long as every one knows what that angle is, they will be able to control their action, will they not?—I do not think so if the angle was very fine: for instance, if she is abeam of you, you would see both her lights.

5009. But no one suggests it under those circumstances; but if you know—assuming it—that every light is screened to 3°, then every vessel knows that if she sees another vessel more than 3° on her bow, she will only be showing herself one light, whereas she will see two from the other one. If she knows that state of things exists she will know what to do; therefore, so long as both vessels know what the screening of each other is it does not matter what the screening is, does it?—I do not agree; I think it does matter very materially. It is impossible at night to know the exact course of the two vessels. I should like to say further that you would be leaving these vessels absolutely without rule—you leave them with no rule at all.

5010. (*Rear-Admiral Andoe.*) By day when ships meet one another nearly end on, the three masts are in a line or nearly in a line, are they not?—Yes. If you put that before you, I think you will understand (*producing a diagram*).

5011. But if the masts are open at all, and slightly on your starboard bow, you do not, I think, cross that vessel's bows to get on to the other side of her, do you?—It depends entirely upon circumstances. If the two vessels are steering parallel courses, no.

5012. I am speaking now of parallel courses?—No; if there was room to pass, certainly not.

5013. Then, instead of crossing the bows, you would give her a little more room, giving your vessel starboard helm, would you not, by day?—Very possibly; but it would depend upon circumstances.

5014. But I mean that there would be no reason for crossing her bows as long as you saw that the three masts were not in line with one another, that they were open, and you had her on your starboard bow?—Pardon me for saying that the masts of the vessel *B.* are all in one line as she is approaching the vessel *A.*, except that she is not absolutely end on.

5015. I am not speaking of your diagram now but simply of two ships passing in parallel courses in opposite directions to one another?—Then in daytime undoubtedly if a vessel is either on the port bow or on the starboard bow, you would not alter your course unless you found you were getting so extremely near as to render some slight touch of your helm necessary.

5016. But then would you cross her bows or keep on the side on which you found her?—If there was room to pass, I certainly should not cross her bows.

5017. But you would give starboard helm, supposing you are on the starboard bow, and keep away on the bow on which you are meeting her?—In daytime.

5018. If it were practicable, would it not be desirable to follow that rule at night, instead of crossing a vessel's bows?—I do not think it is possible.

5019. These rules were made 23 years ago, when the average speed of ships, I suppose, would not be more than 10 or 11 knots at the outside?—Yes.

5020. Now when vessels approach at a much higher speed and attempt to cross one another's bows, they are apt to pass very close to one another much more so than in former days when they were going at a much lower rate of speed?—If you give your vessel too small a helm, certainly.

5021. I mean the mere fact of going at a greater speed would bring them near together much sooner than if they were going half the speed?—No doubt.

5022. Therefore that appears to me to be a reason for not crossing the bow if you can avoid it?—I have not the slightest doubt that hypothetically you ought never to cross a vessel's bows, as I pointed out in the paper you have before you, if you can help it, but at night you do not know how the vessel, which is 3° or 4° on your starboard bow, is steering with reference to yourself, and according to the present regulations for preventing collisions at sea you would port to such a vessel. I know that case has been considered over and over again by different Rule of the Road Committees. I have been on a Rule of the Road Committee ever since the end of 1873, and the conclusion that always has been arrived at was that it was far preferable that vessels steering parallel courses when on each other's starboard bow should starboard, but the difficulties in the way of such a rule were extremely great, and it was thought it would not do to have one rule for a vessel fine on your port bow and another rule for a vessel fine on your starboard bow, and I am afraid that if you had two different rules it would lead to a great deal of mischief.

5023. I do not see any reason for altering the rule, but supposing the alteration of the screening was made, say, for argument sake, we determine to make it finer, the rule would still hold good, that if you sight the vessel's both lights nearly ahead you would port your helm?—Certainly.

5024. But supposing you only sighted the vessel's green light nearly ahead?—Yes.

5025. According to this rule it says that if you only see the green light it is perfectly safe to continue your course?—Yes.

5026. If the lights were screened fine it would be very unsafe to continue your course, but green to green would mean that each vessel ought to give starboard helm to keep clear of one another in that case?—Yes.

5027. I am presuming now that they never sighted both side lights?—Yes, that is so.

5028. Therefore this rule which you refer to here at page 7 would require alteration?—Most undoubtedly, it would not be applicable to fine angles of screening.

5029. This was made to apply to vessels when they were screened at a much coarser angle probably than now?—Yes, I think that is very probable.

5030. And when the speeds were very much lower than than they are now?—Yes, certainly. I do not think it matters very much as to the speeds of vessels, because you must remember that, although they are approaching one another at so much greater speed, still the transverse distance is also performed in shorter time.

*Sir D. Murray.*

18 July 1895.

5031. You see a long ship covers a great deal of ground in making a circle, and so far as my experience goes no officer will give a very large helm to clear a ship unless there is absolute danger?—For myself, I have tried to to put it within narrow bounds. I have said porting one point might do, but I have never ported to such a small extent in my life. I have ported two or three points. The helm should be ported at once, and as much as possible, if there is any danger of collision.

5032. But you cannot always do that at sea, I have often seen vessels pass one another with a very slight helm, and very little alteration?—I think that is very rare; with large and swift ships they generally take abundant care to keep out of the way. The officer in charge, say, of one of the White Star ships does not know what any "tramp" that he meets on the ocean may do, and he takes very good care to give that vessel, where it is practicable, such a wide berth that no error of judgment on the part of the officer in command of the "tramp" will prejudice his safety.

5033. Then, if he only sees the green light, he would naturally give starboard helm——

(*Mr. Ismay.*) And plenty of it.

5034. (*Rear-Admiral Andoe.*) And plenty of it; but he would not give port helm, and cross the other ship's bows to sight his light?—No, swift ships in these days do pretty nearly what they like; the regulations were not made for vessels of that kind. Speaking of my own experience, I never paid much attention to the regulations for preventing collisions, but whenever practicable gave other ships so wide a berth as to render collision impossible, in which case, of course, the regulations did not apply.

5035. But in legislating for ships, you must legislate for all classes, so that they will keep clear?—Yes, not only that, but you must legislate for those men who have not great experience or ability.

5036. But it appears to me that as long as the rule remains the same when you sight both lights ahead, or nearly so, and then you give a port helm, the angle of screening would give rather more latitude for giving starboard helm instead of port helm?—Only the unfortunate thing is that in either of those cases the one ship would see both side lights, and the other ship would only see one; therefore, one might port, and the other might starboard; which is what I pointed out in my diagram.

5037. That would be possibly due to yawing?—No, I do not think you can pay very much attention to yawing. I know no more fruitful cause of collision. You have a young or inexperienced officer in charge; he sees first the red and then the green, or first the green and then the red, and at once says, "That vessel is altering her helm," and, in the first instance, he puts his helm hard over one way to clear her; then she yaws suddenly and shows the other light, and he puts his helm hard over the other way; when he sees a collision is likely to happen he puts his engines full speed astern and loses all command of his ship, and so the collision occurs, whereas if he had persevered in his original change of helm he would have gone clear. I can only say that in my experience at the Board of Trade since 1873 I know of no more fruitful cause of collision.

5038. If a vessel yaws and shows her two lights you must deal with it as two lights ahead, whether it is due to yawing or to alteration of the course?—I think not. It is generally safe to port as lights are screened at the present time, but I am very much afraid that if they are screened to a very fine angle it would be productive of very grave mischief. Of course that is only the opinion of one man.

5039. (*Mr. Ismay.*) I should just like to ask you in reference to the position of side lights and the masthead-light; there is a tendency to put the side lights into screens just abaft the forecastle?—Yes.

5040. What is your opinion as to the best place?—My opinion is that you ought to allow the shipowner to place his side lights in any position on board the ship that he thinks proper, provided always they comply with the regulations. I do not believe that placing the side lights at a definite angle with regard to the masthead light would do any good. The subject has been threshed out over and over again. I very much doubt whether in practice you would ever be able to insist upon a definite angle; there are many things which lead the shipowner or the shipmaster to determine in what particular position his lights should be carried, and I do not think you can have a hard and fast rule which would be applicable to all cases.

5041. But supposing that you did make a recommendation in that direction, would it be in favour of placing the side lights abaft the masthead light?—I certainly think it is far preferable, because, as you know, in many of the long passenger steamships it is absolutely impossible to carry them forward of the masthead light, unless they are carried in towers, and those towers would be so constantly washed with salt water that you would get an incrustation of salt upon the glasses, and it would be very difficult to see the lights.

5042. It is because I had in my mind a passenger steamer carrying her lights in those towers that I was pressing you upon it?—I strongly object to towers myself. I cannot object to them officially, but still I do not like them; my opinion is dead against the tower.

5043. (*Rear-Admiral Andoe.*) Would Sir Digby Murray say what he thinks the best position would be if it was optional?—I think the best position for the side lights is the bridge; if there are two bridges, an upper and a lower bridge one above the other, I think, if possible, they should be upon the lower bridge, when I think the officer of the watch will have more attention paid to them, and I think it is the preferable position on board ship in which to have them.

5044. (*Sir E. Harland.*) Quite irrespective of any angle from the masthead light?—It is some years now since I went into that subject, but it was gone into thoroughly at the time by Mr. Thomas Gray and myself and some others, and the conclusion we came to after thoroughly inquiring into the subject was that it was impracticable to have a hard and fast rule for all ships.

5045. (*Captain Halletl.*) Could you tell me how often the lights of vessels are examined with regard to their screening?—I could not answer that question. We have comparatively speaking a small staff considering the duties which they have to perform, and there is always pressure put upon the Board of Trade to decrease their staff. I am afraid that a good deal of the anomalies, so far as the difference in screening is concerned, are owing to the surveyors not having sufficient leisure to inspect all the ships afloat. There is an enormous number of vessels in the Merchant Service, and I have no doubt that many escaped observation altogether.

5046. In the case of passenger steamers, how long do the passenger certificates last?—It all depends; if she is in a satisfactory condition in every way, and we have no doubt about her, then the passenger certificate is issued for 12 months.

5047. Are the lights included in the certificate?—There is a separate certificate for lights, but the lights are inspected every time the ship is inspected for her passenger certificate.

5048. Then what power have the Board of Trade to insist upon a correct angle of screening, and what happens if they find that that angle has been altered after the passenger certificate has been given?—Well, they can insist upon having the vessel's lights re-screened. But we have no guarantee whatever that a ship's lights may not be altered within a week.

5049. That is what I mean?—Until you get a regular pattern, what I may call a statutory pattern of side lights, you never will be safe. There was a case I heard of only the other day, where on one side of the ship one side light had been passed by the Surveyor, and on the opposite side they put a spare light which had not been passed, which consequently was showing at quite a different angle to the other.

5050. You said yesterday that you had never seen a lamp with the inner edge of the wick and the inner edge of the lens in the same line?—Yes.

5051. With reference to the misprint in the Instructions of 1875?—Yes?

5052. If the reading ought to be "lens" and not "wick," what possible good could that be to the angle, because the angle would be to the light, and not the lens?—All I can say is, that it was the merest rule of thumb; up to 1892 it depended entirely upon the position of the wick in the lamps. It depended also

upon the housing of the inner edge of the lens. The whole thing was purely rule of thumb.

5053. But it appears to me that the "inner edge of "the wick" was to obtain the proper angle, and that it could not have been a misprint?—No, it never was intended; that I am certain. I have asked our officers who have had experience of screening lights prior to 1892, and they all tell me the same thing, without one single exception. Besides this if the word wick is not a misprint for lens, then you have this greater anomaly, namely, that the preceding paragraphs, which are in direct contradiction to this wording, have been printed in error, and that all the diagrams have also been printed in error.

5054. (*Mr. Bolam.*) In the paper of further evidence, which you have handed in just now, you have the words, "In former times the screening was from the "centre of the wick"?—Yes.

5055. Would you kindly give me the reference to the instructions? I have not been able to find any?—I cannot say it is in the text of the instructions, but it is shown in the diagrams. Those are the old diagrams,* and you will see a black dotted line. That is the line which indicates the angle of screening, and that, in every case, is drawn to the centre of the wick.

5056. And that black dotted line has always been in the diagram, has it?—Always. Those diagrams have been cut out of the old instructions. The only alteration is the red lines which you see there indicating the angle.

5057. When you make the alteration in the lamp table and correct the average of the angles which you yourself pointed out yesterday was 4° 2′ instead of 4° 30′, will you kindly take care that the words are "not exceeding 4°," in order to make the correction absolutely perfect?—I rather think I worked out all Mr. Ramsay's examples, and I found that the addition of the screen averaged 4½ inches, though in one or two cases they ran to 5.

5058. But these lamps were to be used previous to 1892, and many of them would be fitted with screens, which came much more than 36 inches in front of the lantern, and they might therefore have been used with longer screens?—I have no doubt whatever far longer screens were used, but then at the same time the depth of the chock was smaller—the longer the screen the smaller the depth of the chock.

5059. So you are quite sure that the chock was only 36 inches before the front of the lantern?—Oh, not at all. In many cases it was 4 feet and over. But what I say is the depth of the chock was diminished; the longer the screen the smaller the depth of the chock.

5060. I have not noticed anywhere that you have dealt with the glare of the lamps in the ships. It is a thing which has been complained of in connexion with the new rule of 4° screening. In the old regulations are the words, "Care must be taken that the "screens are 3 feet long, or such greater length as the "position of the light with regard to the screen, and "the distance from the head of the vessel, may render "necessary." If, therefore, side lights were placed well aft under this old rule, and the secondary rays from the lamp crossed within the stem of the vessel itself, then your surveyor could make the screen longer. But with your 4° instruction you have cancelled that power?—But we should never permit the lights to be carried well aft in the vessel.

5061. Then your 4° instruction is, to some extent, interfering with carrying the side lights well aft of the foremast?—Not well aft of the foremast; but we require that the side lights should either be forward of the extreme beam of the ship, or, at all events, that they shall be outboard of the extreme beam of the ship.

5062. With a 4° angle of screening, and the glare from the lantern, you will have an angle of about 8° of light, and if the lights are well aft, then they are sure to have the glare on the forecastle of the ship?—All I can say is, that I have stood forward in many ships, and in or two steamers I have been aboard of lately I could not see any. Mr. Denny the shipbuilder whom I daresay you know very well has just returned from a voyage; he was on board a vessel which carries the electric light and he told me he went purposely and stood at the stern of the vessel, and he could not see the lights without leaning over two or three feet one way or the other.

5063. In answer to questions 82 to 86 in your first day's examination some weeks ago you gave us your view of the meaning of the words "right ahead" in the Regulations for Preventing Collisions at Sea. Do you mean to imply that the word *horizon* in that regulation is a visible horizon of two miles radius? Your words seem to imply that?—I do not think that that was the meaning. All that I meant was that the lights when viewed from right ahead or from an angle of 45° ahead, say four points, should show the same volume of light at all distances at which they might be observed, and although in many instances this has not been the case, practically speaking in a great many it has; and we always required the artillery officers at Shoeburyness when holding experiments to state precisely whether the side lights conformed to that rule or not.

5064. You said that the Board of Trade have always understood "right ahead" in your regulation to mean right ahead of the ship?—Yes.

5065. Mr. Charles Hall, now Sir Charles Hall, at Washington made a statement on the subject. I do not know whether you concur in it or not. You were not a delegate yourself?—I would rather not be asked for my opinion upon anything that Sir Charles Hall has said, if you do not mind; I am quite willing to give my opinion upon any point.

5066. Then I may take it that when you gave that answer which I am speaking about, you did not mean to pin yourself to the opinion that the word "horizon" meant the horizon of two miles radius?—Oh, no, it was merely the arc of the horizon, not the radius of it.

5067. You have said in a paper* you have handed in:—"I am inclined to think the grievance of the pilots "is a sentimental one."—How would you provide against their objection?—I have already stated in one of the papers,† though I do not think it necessary, that the side lights might be placed back to back at the stem of the ship, with a screen of sufficient length to prevent those lights from blending.

5068. In regard to the connexion between screening and collision, I think your view is that the 4° angle will prevent the yawing of a vessel being mistaken for a change of helm?—Oh no, I never said that.

5069. I think in one of your papers you did?—I dealt with the question of yawing in one of the papers.

5070. I think you put it this way; that the yawing of vessels which makes the vessel *A.* appear to show first the red and then the green or the green and then the red to another vessel is very often likely to be taken to be a change of helm, and that is likely to be avoided by making the angle as large 4°?—I have never said so. Yawing has been put forward in defence of a very fine screening, and all I wished to show was how unreliable a defence it was. I have not gone on to say that the 4° screening will prevent this mistake being made.

5071. Then do you think 4° is too small to check any fault of yawing?—No, I do not think any angle you can possibly give would prevent yawing.

5072. Not prevent yawing, but prevent the yawing from being mistaken for a deliberate change of helm?—I am very much afraid that officers and commanders of ships would make that mistake whatever you did.

5073. Therefore one need not regard the 4° angle in connexion with yawing?—Certainly not.

5074. The use of the steering rules in the regulations is to avoid collision after risk of collision is involved?—Yes.

5075. And the use of the side lights is to avoid risk of collision before risk of collision is incurred?—Yes, those regulations are not applicable really till some risk is incurred.

5076. But then first you have side-lights, the object of which is to avoid risk of collision, and then you have steering rules, which are to avoid collision after risk of collision is incurred. I mean the rules and the side lights do not cover the same ground?—I think you must consider the two points separately; the application of steering and sailing rules, and the angle that it is necessary to screen the lights to in order to permit of the whole volume of light being seen ahead, especially in thick and foggy weather.

5077. I asked you that question because the two things have been somewhat mixed up by some of the witnesses. The essential point to aim at in the screening of lights is uniformity?—Undoubtedly.

* *See* Appendix 1, No. 2.

* Appendix 2, No. 7. † Appendix 13, No. 2.

*Sir D. Murray.*

[18 July 1895.

5078. You want to prevent one vessel showing a good visible light more across her bow than another vessel does?—Yes.

5079. And that is especially desirable in thickish weather, where, as you say yourself, there is more risk of collision?—Yes.

5080. Now thick weather cuts off the reduced rays of the wick very much more rapidly than it would cut off the full rays?—What do you mean by the reduced rays.

5081. The rays from a part of the wick as distinguished from the full wick?—I think I called attention yesterday to the 1893 experiments, and in those experiments, at 500 and 1,000 yards, the lights all showed to the theoretical angle from the outer edge of the wick, and the light shown by the extension of the flame beyond the wick and also the reflection from the lens were totally invisible at those distances.

5082. So that in thick weather the reduced rays would be practically invisible?—Yes.

5083. And what you would have to depend upon would be the full light from the full wick?—Exactly.

5084. When you make a rule of screening from the outside of the wick, the more nearly a physical point your source of light becomes the more completely you would be throwing the whole of the 4° across the opposite bow?—I am not quite sure that I follow that.

5085. Granting that you have a rule for screening from the outer side of the source of light, the more nearly your source of light becomes a physical point the more completely would you be throwing the whole of the 4° across the opposite bow?—Well, does that not depend upon where the whole flame of light is?

5086. I am assuming by my hypothesis that the source of light is as nearly as may be a physical point?—If it is a physical point at the outer edge of the wick undoubtedly that is the case.

5087–8. If it is a physical point there would be no inner or outer edge, it will be simply a physical point. I am supposing that your source of light is simply a point of light and not a wick at all. Supposing it is a single film, for instance, as in the electric lights, the more nearly you screen that to 4° across the opposite bow the more nearly completely will you be throwing the whole flame of light 4° across the opposite bow?—No doubt.

5089. Therefore if you have two ships under your existing rule of 4° screening, one of which has a light, say, of the electric type, which is almost a physical point, and another vessel has a wick, a pretty broad wick, one vessel will be throwing practically the full light 4° across the bow, and the other will be showing the full light at a less angle than 4° across the bow?—I think this, at the present moment, is purely hypothetical. I have had no experience whatever of the screening of the electric light, and I think after your experiments I shall probably be able to gain from you a good deal more than I know at present.

5090. But leaving it upon the ground of mere hypothesis, that would be the case; that if one vessel had a powerful light practically concentrated at a physical point, and the other vessel had a light with a pretty broad wick in use, the first vessel would throw a full light almost 4° across the opposite bow, whilst the second vessel would throw the full light at a smaller angle than 4° across the opposite bow, and especially in thick weather where the reduced rays of the wick light are cut off?—That is very possibly the case.

5091. Then in thick weather what your 4° instruction will do is this, that taking two vessels of these types you might have one of them showing the light which is distinctly seen at a greater angle across the bow than the other one is doing?—Undoubtedly.

5092. And therefore you will be by that method of screening creating the very evil you wish to avoid of having ships' lights in dangerous weather practically showing at different angles?—Well, yes, to a certain extent they would.

5093. I put that as the outcome of your method of screening apart altogether from whether the angle is 4 or any other number of degrees?—You see unfortunately the angle of screening to ensure uniformity must be the same for all ships, but if future experiments show that it is not necessary with the electric light, then I presume an alteration will be made in the instructions.

5094. The best plan evidently will be, will it not, to make a rule which will be useful for a long period of time, in view of the increased probability that the tendency will be to increase the full light? At any rate, is it not more necessary to deal as the regulation prescribes with the full flame of light, rather than to deal with the reduced light?—Providing it is practicable, yes.

5095. If you could do that then it would be best?—It would undoubtedly be best to deal with the full flame.

5096. There appears to be only one solution of that; that is to screen your source of light to the inner edge fore and aft of your chock, and to fix the angle of the outer edge, which you can fix at anything you like, call it N degrees, for example, and you can make that angle be absolutely constant in all ships by simply varying the length of screen according to the size of the source of light?—That is rather hypothetical, and I think in the future it will require very careful consideration and a lot of threshing out.

5097. Of course you have already said there was no possible way of getting over the boundary line between meeting and passing; the boundary will always exist?—To a certain extent undoubtedly, so far as small angles are concerned.

5098. Might it not exist also with regard to large angles?—I do not say that.

5099. If, instead of calling the angle 4° or any number of degrees within which you might consider vessels to be meeting vessels, you call it N degrees; then when you get to the number of N degrees you get to the number of your limit?—Yes, pardon me, I entirely misunderstood you when you spoke about angles; I understood you to mean the angle ships bear from one another, not the angle of screening.

5100. Oh no. There is no possibility of getting over that difficulty, is there?—No, except the finer you screen the greater difficulty there will be, because you cannot screen with absolute mathematical accuracy, and for other reasons, which I need not recapitulate, because it is all contained in my evidence.

5101. There is no doubt that vessels meeting are in danger?—Well, yes, certainly.

5102. And vessels passing are in safety?—That depends upon the direction in which they are passing.

5103. But if they are passing in the modern sense of showing green to green and red to red there will be, in the words of the rhyme, approximate safety at any rate, if not perfect safety?—Yes, provided they were both showing the same thing.

5104. I am using the word "passing" in the sense in which it is ordinarily used at sea, in the sense of vessels passing showing red to red and green to green; I am using it in that sense only?—Still you must remember when vessels are approaching one another at a fine angle, one of those ships may be showing both side lights and the other only showing one.

5105. The general opinion of officers of the Merchant Service who have been examined is that the angle should be as small as possible. They all seem anxious to convert *meeting* into *passing* as soon as possible, and for that reason they desire that the angle should be at a less degree. You do not concur in that?—I do not concur in it, and I very much doubt whether they have given the matter very careful consideration. It has been under consideration for the last 23 years and more in the Board of Trade, and long before I joined it.

5106. Have there been complaints from ships in cases where the angle of screening has been lessened?—No, I can tell you of one man in your own neighbourhood—I will not mention his name—who wrote to the "Nautical Magazine" and to "Fair Play" and other papers, pitching into the Board of Trade and the screening, saying that his lights always had been screened parallel to the keel, and when his lights came to be examined he found they were both screened to 6°, and not only his but every vessel belonging to the fleet were screened to 6°. He then wrote to the "Nautical Magazine," and to "Fair Play" to try and take back what he had said. I saw a copy of his letter, and he afterwards wrote to the "Times" to the same effect, but the letters were never published. They published all the letters in which he pitched into the Board of Trade, but none of them when he withdrew what he had previously said.

5107. But in cases where ships have had their chocks cut down; masters of ships who have come here have complained of cases where an addition has been made to the chock; have the Board of Trade any record of complaints of that kind?—No; but in numberless instances when the surveyors have gone on board a ship to screen the lights, the master has said, "No, "I am not going to permit you to interfere with my "lights; they have been screened in a line parallel "with the keel, and I am not going to allow you to screen them to the 4° angle;" when the master has been persuaded to see what angle the lights were actually screened to, they have been found to be screened to 6° and over.

5108. Usually over 4°?—I will not say usually. I have only the statements which you have already seen, sent in by the Principal Officers.

5109. Officers in the merchant service do not have the means generally—take tramps, for example—of taking a very fine bearing. They could not take a bearing and determine that it was absolutely 4° on either bow, could they?—I do not believe they could exactly in any ship; and then, of course, the bearing depends upon whether you are standing in the middle line or at the side of the ship.

5110. So that in taking bearings to say whether an object is 4° or 3½° on your bow is a practical impossibility in navigation?—Certainly; nor is it necessary in vessels so long as they show both side lights.

5111. In regard to surveyors, tables have been put in showing a very large number of vessels which were screened to 4° when the surveyors examined them in 1893; there just seems to be a doubt as to whether or not any, all, or none of these vessels had had their lights screened after the introduction of the 4° instruction, and before the surveyors who handed in these reports saw them. I asked the surveyor from Liverpool how we could determine when a vessel is altered, and that seemed to be a very roundabout process, not capable of being carried out by any surveyor?—I can only put in the tables for what they are worth; but, as I said yesterday, it was entirely contrary to the interest of all the surveyors to report all this lack of uniformity, because, although they had the excuse that they had no definite instructions before 1892, still they cannot have considered, and I do not consider, that it was a satisfactory state of things.

5112. Mr. Gray's rhyme "green to green," you think, was meant for large angles of screening?—I think so, undoubtedly.

5113. Would you say precisely what you mean by large angles. I presume you do not mean angles of 10° or 12°?—No; I have had to investigate the matter very closely since all these sensational attacks have been made upon the Board of Trade. I always imagined the angle to which the lights were screened was about 3° from the centre of the wick, that is, generally speaking, about 4° from the outer edge, but I have since found that, in many cases, the angle would be greater.

5114. And that, you think, is the angle Mr. Gray had in his mind when he wrote that rhyme?—I am confident it is, because you see I was in communication with Mr. Gray for a very long series of years. I was his colleague on the Rule of the Road Committee, and the Thames Traffic Committee, and all these points have been considered, both by him and myself.

5115. And if the angle were reduced from 4° to a somewhat smaller angle, do you think the value of the rhyme would be less than it is just now?—Yes, I think it would be if you materially reduced it, certainly; and then there is another thing, you must remember it is very difficult to make substantial alterations in that rhyme, which is quoted very nearly by all nations on the face of the globe, eastern as well as western, and if you were to have such an angle of screening as would vitiate that rhyme without due warning it would be very dangerous.

5116. Do you think the service regards this rhyme as anything but a very rough and ready thing?—Well, all the regulations are rules of thumb; when you have a large committee like the Rule of the Road Committee, no one member has entirely his own way; you have to give and take. I do not say the regulations for preventing collisions at sea are all they might be—I do not think they are—but upon the whole I think they are the best we are likely to have, and change is always dangerous, very dangerous so far as seamen are concerned.

5117. I wish to point out to you that you have shown very strongly that the risk of collision occurs with vessels which are approaching nearly end on, very little on the bow, and the puzzle is to know in one vessel what the other is going to do. When two vessels are meeting almost end on there is considerable difficulty in the minds of both officers to know what the other is going to do. One may port and the other may starboard?—There need not be if they make use of the voluntary sound signals.

5118. In the Revised Regulations, which are not law yet, but which will probably become law shortly, steamers when they see each other, which alter their helms, will be compelled to use sound signals, so that that difficulty will disappear?—Yes.

5119. Therefore, upon any view of the difficulty about fine angle of screening and the dangers it may result in, we must view them now in connexion with the new rule?—Yes, but I rather think you must regard the new rule in this way, that the new rule only enables a vessel to do what the regulations require her to do. It does not follow that because a man makes a signal "I am "going to starboard," that he has a right to starboard, or that the other vessel should starboard also.

5120. But if this vessel is in one of the numerous ambiguous situations which we have in the regulations, where the officer must use his own intelligence, and where it comes under the Article "Nothing in these rules "shall exonerate any ship, or the owner or master or "crew thereof, from the consequences of any neglect to "carry lights or signals, or of any neglect to keep a "proper look-out, or of the neglect of any precau- "tion which may be required by the ordinary practice "of seamen, or by the special circumstances of the "case." The whistles will indicate what each is going to do?—Providing they both act in the same way.

5121. Where one is porting, and the other starboarding they will both have time to stop and reverse?—I regret to say there have been many cases where vessels have given the proper signal, and it has not prevented a collision. In the United States there are signals which work well, and I have been familiar with them for 40 years; I mean the river signals, which are somewhat different to those now proposed. For instance, take the Mississippi river, where there are a number of wood piles, and the steamers put into these wood piles to get wood for their fires. A man may tell a vessel coming towards him that he wants to go to a wood pile on the opposite side of the river to that which he ought to be on. Say that he wishes to starboard, he makes the signal to the approaching vessel that he is going to starboard, but he has to wait for a responding signal from the other vessel, and if the other whistles "no, port" he must not go across until the other has passed. We have no such regulation as that with our voluntary signals, and I think it would be difficult to have it at sea.

5122. Of course the system will no longer be voluntary with the new regulations in force?—I think it is a very great mistake to have them voluntary. They ought to be compulsory. In the Thames Traffic Report, which I have laid upon the table, you will notice that many of the witnesses, especially the pilots, were very indignant at the idea of these signals being compulsory. They said they might produce very alarming collisions on the Thames. Subsequently, however, the pilots came to the Conservators for an additional signal, and they said they would not have the others taken from them on any account.

5123. I suppose these signals would not lead to any mistake at sea. Vessels are hardly likely to make the signals at the same time?—It depends upon how near they are to one another.

5124. (*Mr. Scrutton.*) Are you practically acquainted with the way in which the surveyors read these regulations of 1894?—In what way do you mean?

5125. You have your own opinion, sitting in your own office, but have you any experience of the way in which they act?—I am not aware that there is any doubt as to the application of the Board of Trade instructions.

5126. In article 8, with regard to the side lights and the 4° angle, it says, "Surveyors are to insist." In article 10, with regard to the lens, it says, "It is desirable"?—That what is desirable?

*Sir D. Murray.*

18 July 1895.

5127. That the lens should be the arc of a circle?—I think that is as much as we can say, that it is desirable.

5128. They do not reject them altogether, if it is not so?—I do not think we have any statutory power to do that. We must show that the light does not show in the manner required by the Regulations before we condemn it.

5129. Then with regard to the different tints; you say here that you supply the tints to the districts?—You were not here yesterday, I think, when I laid them on the table.

5130. To your own knowledge, when surveyors go on board a ship, do they always have this box of glasses with them?—I have heard lately that, in the case of one surveyor, he had not the box; but it is intended that they should carry the box about with them, and that they should compare the tints of the lenses with these patterns.

5131. Your impression is that they very often do not have them, I suppose?—Until two or three days ago I was always under the impression that they had them, but I understand this is not so always.

5132. (*Rear-Admiral Andoe.*) Are surveyors always supplied with this box?—Yes, every single district in the country; I think we send five to each district.

5133. (*Mr. Scrutton.*) There are 15 surveyors at Liverpool?—Yes, but then every surveyor is not employed at the same time in screening side-lights.

5134. (*Sir E. Harland.*) Reference was made just now to the use of sound signals for making known whether a ship is going to port or starboard. Would it in your opinion be an advantage, where two vessels are approaching one another, and they are each not sure what the other is going to do, that one should be able to indicate to the other what course she is going to take?—I think that wherever two vessels are in sight of one another, and are approaching, that they ought to tell one another what they are going to do; therefore these signals ought to be used in every case.

5134*a*. (*Mr. Ismay.*) In the large steamers using electric lights, would you see any objection to their screening their powerful lights to a finer angle?—Not at all, providing you get the same field, I think you ought to try to get the same field in all ships where practicable, but I have myself so very little knowledge about electric lights, that I do not care to venture an opinion.

---

## Wednesday, 24th July 1895.

PRESENT:

THE RIGHT HON. SIR FRANCIS H. JEUNE IN THE CHAIR.

| | |
|---|---|
| Rear-Admiral ANDOE. | Captain CASTLE. |
| Captain BARKER. | Captain HALLETT. |
| Mr. BOLAM. | Mr. SCRUTTON. |

Mr. C. HIPWOOD, *Secretary.*

*Staff-Capt. Phillips.*

24 July 1895.

Staff-Captain PHILLIPS called and examined.

5135. (*Chairman.*) What office do you hold, Captain Phillips?—At the present moment I am commanding the "Fire Queen."

5136. What is the "Fire Queen"?—She is a small ship, a tender to the flagship at Portsmouth, and the yacht of the Commander-in-Chief of Portsmouth.

5137. Perhaps you will kindly tell us what your sea experience has been?—44 years I have been actually serving in the Queen's ships, or nearly so.

5138. Have you commanded any ships?—I have commanded one or two small vessels: but my principal work has been as navigating officer of ships.

5139. That is the capacity in which, I think, we are anxious to have the advantage of your evidence. Have you been a navigating officer for many years?—Yes, for many years, since 1857. My last service as such was five years in the "Minotaur," the flagship in the Channel.

5140. Taking such a vessel as the "Minotaur," and the larger class of vessels, what are the red and green lights that they use; are they electric or oil?—The "Minotaur's" were oil lamps, but all the new ships are now fitted with electric lamps; nearly all the modern ships are fitted so that either electric or oil lamps can be used—all the large ships and nearly all the others.

5141. How is that managed? Is the oil light exhibited or ready to be exhibited over the electric light, or does one have to be substituted for the other?—One is substituted for the other; the connection is made through the light box, which is generally used. In the event of any accident to the electric light then the ordinary oil lamp, such as I have a specification of here, is used; but Captain Noel can speak more particularly upon that point, because he has just served for three years upon a ship where this electric light has been used; he can tell you from personal observation.

5142. In the more modern ships are the lights in light turrets, or how are they placed?—I have brought you a sketch of the last Admiralty Order, upon which all the modern ships are based—full sized.

5143. You call it the lantern box?—Yes; this is the Order that bears upon it (*produced*); all the modern ships are more or less fitted in that way. The ships now are similar in construction, with the bridge well forward, the fore part of the ship low, and the lights shown from the sides of the bridge, and practically now all the new ships, except the very small boats, are fitted with this description of light fittings.

5144. This represents the port light, I suppose?—That is the port light, with the metal screen; it is drawn to scale.

5145. (*Mr. Scrutton.*) What is that?—That is showing the side view—a section, so that the light must not be obscured when the ship is rolling 30 degrees.

5146. (*The Chairman.*) I do not quite understand then what this represents?—That is the screen for shading two points abaft the beam—a metal screen; that is the system upon which all the modern ships are based, as far as structural arrangements will admit.

5147. (*Rear-Admiral Andoe.*) How long has that been in force?—I think since 1890.

5148. (*Captain Barker.*) That is built in the ship?—It is generally fitted on the side of the bridge. I have here the Admiralty Confidential Order for fittings. I had this full-sized drawing made so that I could leave it if it was of any use to you.

5149. (*Rear-Admiral Andoe.*) Is that the book supplied to the dockyard?—To the dockyard for fittings. This of course would be private; it embraces other things—fittings of guns and other matters.

5150. (*Chairman.*) Is this lantern box a fixed structure?—Yes; the lamp drops in from the top. The

top of the box turns up on a hinge and the lamp drops in so that the bottom of the lamp fits into place, and when it is in there the lamp cannot twist, or turn about, or move either way, so as to alter the angle.

5151. (*Rear-Admiral Andoe.*) The box is not glazed, is it?—Oh, no; there is an open hole *here*, coincident with or opposite to the glass of the lamp.

5152. It is not glazed, there is no glass in the box itself?—No.

5153–4. (*Chairman.*) When you have the 3-feet screen, do you have a chock?—I went round every ship in the Fleet Reserve, and I have tabulated what I found here so that I thought you would be able to see the particulars at once. The table* embraces specimens of the modern ships and a good many old ones, some have a chock and some have not. "Royal Oak" and "Revenge" are two sister ships, one has a chock and the other none; there are other slight differences too. "Royal Oak" has a wooden chock 4 inches deep. There are here specimens of all ships built, battle ships, first-class cruisers, second-class cruisers, and smaller ones.

5155. Where there is no chock I suppose the screen is so placed that it operates as such?—Yes. The principle is carried out so that the light is cut off as directed.

5156. Where is that 3-foot screen measured from—is it the length between the fore part of the lamp, and the end of the screen?—Yes, and there has been some looseness, as you will see, there. In some cases the chock is not put quite at the end of the screen, and the practical screen becomes less than 3 feet.

5157. I see in one case it becomes as little as 2 feet 6 inches, and in other cases it rises to 4 feet 4 inches?—That is the whole length of the screen. Of course in some of the vessels it is almost 40 feet; in some of the old-fashioned ships, owing to the structure of the ship, the lamp is put on the side of the middle building, and the lamp has been placed to make the angle, so that as a matter of fact the screen has been 40 feet long.

5158. (*Captain Barker.*) The side of the battery, I suppose?—Yes, in some ships. You may take it that the plan I have shown you is the general principle upon which all our ships are fitted now, wherever possible. Of course in some small torpedo boats you cannot possibly do that.

5159. (*Chairman.*) I see in addition to a forward screen, you have a screen for the two points abaft the beam?—Yes.

5160. Now what I should like to ask you is, how do you secure the angle, of these lights?—It is done practically in the first place, the screens now are fitted so frequently; it is more or less laid out in the mould loft to scale, if not in full length, and according to the transverse distance between the lights, or the size of the ship. Both elements come in, whether the ship is very large or the transverse distance is great, then a point is taken 200 yards ahead of the ship, and the screens are arranged for that.

5161. So that instead of having your screen made so as to give a particular angle from a particular part of the wick, or the outside of the lens, whatever it is, what you do is to regulate the lamp and screen so that the lights cross at a particular point?—Yes.

5162. What is the point at which you think it right to make the lights cross?—I cannot say definitely what is the size of the ship or the actual number of feet in transverse distance which regulates it. But in ships with a large transverse distance it is 200 yards, and in ships with a small transverse distance it is 150 yards. There does not seem to be a hard and fast rule; it varies between these two. I have a list† here which shows the transverse distance of a certain number of ships, and the distance from the transverse line to the stem.

5163. In the first one, the "Royal Oak," the transverse distance between the bow lights is 60 feet?—That is from the centre of one light to the centre of the other.

5164. Then the distance of stem from transverse line is 122½ feet?—That shows how far the lamps are from the bows; you will see one or two I have picked out. They are very close forward.

5165. The distance from the stem to the transverse varies very much indeed, and I see in one ship, the "Calliope," it is as little as 13 feet, and it rises in the "Royal Oak" up to 122½ feet, and there are no two cases which are the same. And then you say the distance at which you make the lights cross is something like 150 to 200 yards?—Yes, it ranges from 150 to 200 yards.

5166. (*Mr. Scrutton.*) From the light or from the stem?—From the stem. These are the Admiralty orders that are carried out. I can leave that table of measurements if you wish.

5167. I do not know whether you so adjust the distance as to have any reference to an angle formed by the screen?—No, it is not done as far as I can make out. I have consulted with many of the people that have to do this work practically.

5168. You know the Board of Trade Instructions since 1892 say the lights are to be screened to an angle of 4°. I only want to know if the Admiralty, in fixing their screening, have any reference to that rule, or whether they act independently of it?—No, it is not mentioned, and I have not heard it mentioned by anyone who has had anything to do with it. Those are the orders* carried out—(*produced*)—and the lights are always tested. After the ship is fitted with bow lights, there is a joint test by the constructing department, those who fit them, technical men, shipwrights, and a sailor representing the Fleet Reserve. They have a joint practical test of every ship, and a certificate is given by the officials from the Fleet Reserve that the lights have been tried in place and found correct before the ship is accepted by the Commander-in-Chief as fit for sea.

5169. And that is conducted at Chatham by the Commander of the Naval Reserve?—Yes, and at Portsmouth. One of the constructors give me a practical account of how he carried out this order, and the manner in which the test is carried out.

5170. I see. "Arrangements to ensure that screens are "properly fitted. The Board of Trade regulations "with reference to the following are observed:—

"*a.* Length of screen.

"*b.* Angle of light abaft the beam.

"*c.* Distance ahead for both lights to be seen, &c.

"(*a.*) This is given as 3 feet from front of lantern, "being in a fore and aft line generally.

"(*b.*) The position of screen governing this is obtained "as follows: A temporary screen made to slide, in or "out, is fitted abaft the lantern, and the correct "adjustment made at night. The lantern is fixed in "its place, lighted, and an observer placed some 200 "yards from it, a position two points abaft the beam "being tried, and then on to three points, the slide "being adjusted by signal from the observer to those "on board the ship, until the correct conditions are "fulfilled.

"(*c.*) A distance is set off ahead of the vessel on the "line of keel (200 or 150 yards off), the foremost end of "screen blocked off, until the requirements are met, "the adjustments being made by signal from the "observer on shore. The signalling is pre-arranged "between those in the ship and the observer on shore, "and is done by means of two lanterns carried by the "latter. The Commander of Dockyard Reserve and "foreman of the ship are at the point of observation, "the inspector at the bow light screen on the ship." That shows very clearly exactly what was done. Can you tell me what oil is used?—It is a vegetable oil, no mineral oil is allowed on board our ships.

5171. Then I suppose the wick is a very broad one. What width is it?—I think I have it in a specification here. I will send you up a specification of the wick.

5172. Do you think you can tell us exactly what it is?—I have brought a specification of the Admiralty masthead and bow lights which perhaps you would like to keep, possibly the wick may be described there.

5173. (*Mr. Bolam.*) Would you ask the witness, please, whether that crossing at 200 yards ahead of the ship is a crossing from the inside or the outside of the wick?—I may observe it is the point at which both lights are seen clearly.

5174. The inside?—You clearly see the light, and from this point of crossing the light dies away towards the stem of the ship.

5175. (*Chairman.*) What I understand you mean is, as they walk towards the ship the light diminishes?—

* See Appendix 14, No. 1. † See Appendix 14, No. 2.

* See Appendix 14, No. 3.

*Staff-Capt. Phillips.*

24 July 1895.

The light is seen and first seen clearly at that point; as you walk towards the ship it begins to fade away.

5176. Supposing you were walking towards the ship, you would first lose the rays from the outside of the wick.

5176*a*. (*Mr. Bolam.*) It depends upon whether the witness means the full volume of light would cross at 200 yards or only the faintest rays?—The crossing point is the point at which both lights are seen clearly.

5177. The full body?—Yes. I would simply say the light is seen clearly from that place and from that distance it begins to fade as you near the stem.

5178. There is another point. When the witness says the lights must cross 200 yards ahead of the ship he means ahead of the stem and not ahead of the lanterns. You mean clear of the hull of the ship and not clear ahead of the lanterns, which may be anywhere?—Yes.

5179. Because in the "Royal Oak" 200 yards ahead of the ship means 600 feet plus 122 feet ahead of the lantern?—I am quoting now the Orders: "The "screens ahead should be so fitted that an observer "approaching from right ahead should see the full "rays from a point from 200 to 150 yards forward of "the stem."

5180. (*Chairman.*) I should like to ask about the 2 points abaft the beam. I see the Admiralty think it necessary to have a screen so as to prevent the rays being seen more than 2 points abaft the beam?—Yes, I think if you look through that tabulated list of ships the majority of those have a screen—certainly the new class ones where the light-box is built up on the bridge.

5181. So much for the oil lamps. Now, with regard to the electric lights, have you ever been on a ship where electric lights were used?—No, I have never served upon them, but Captain Noel has; he has just served three years in the "Royal Sovereign," and he will be able to explain that fully.

5182. And I suppose he will know about what sort of filament is used and what sort of lens?—Yes.

5183. As the Admiralty have taken this view about the crossing lights, I suppose you have never directed your attention specially as to the particular angle at which the lights are screened?—The authorities simply carry out their orders, and you see there is a great difference in the length of the after screening; some are screened up to 14 or 15 inches and some are placed at an angle aft of 20 degrees in order to fulfil the requirements. Of course the same principle is aimed at all through, cutting off the light to be seen a specified distance ahead, and also the regular distance and angle abeam; the full light only at 2 points abaft the beam, and never more than 3. There is one thing I should like to point out in our ships. I do not know whether it is so in the merchant service, but several of the screens in our ships are so arranged as to fall back, to turn in-board, either altogether, or a part of it on a hinge. In my opinion, speaking as a sailor, it should be forbidden, because the screen may be left in and forgotten, and the light may show across the bow and cause the very trouble which this question of screening is trying to prevent.

5184. Now, although you have not considered the question of screening, I do not know whether you have formed a view as to whether fine screening is preferable or not to coarse screening. You know that is the question which this committee has to consider. The Board of Trade have taken the view that it ought to be at 4°, and other persons think it ought to be much finer; but apart from the particular angle at which it should be, have you formed any opinion whether fine screening is better than coarse screening?—I should like to get in between the two extremes. I think moderate screening would be right. I think that coarse screening leads to your seeing the light too much across the bow, and in very fine screening you may be nearly ahead, all but ahead, and not see the other light.

5185. But supposing you can ensure that you see the light at a perfectly sufficient distance ahead, so that there can be no question of there being any obscurity ahead of the vessel, can you see any object in having the light screened more coarsely than is sufficient to effect that object?—No, I do not.

5186. (*Rear-Admiral Andoe.*) Perhaps Captain Phillips is not quite aware of the contention which at present exists between the Board of Trade and shipping interests upon this point, and I should like to explain to him that the old instruction the surveyors in fitting lights in merchant ships was "If the surveyor finds that the red "and green rays cross each other, he should, of course, "have the defect remedied at once. There are many "ways of doing this, for example, the screen may be "lengthened, or another board may be placed outside "it (fig. 4) or a chock (equal in thickness to the distance "between the inner edge of the lens and the side of the "screen) may be secured to the fore end of the screen "(fig. 5), or the lamp may be so placed that the outside "of the screen will come against the inner edge of the "lens (fig. 6); or the screens may be so placed that the "distance across the ship between their outer sides at "the fore end shall be equal to the distance between the "inner edges of the lenses of the two lamps (fig. 7). If "the red and green rays cross each other immediately on "passing the stem, the red light will be seen on the "starboard bow and the green light on the port bow, as "shown in fig. 8, but, on the other hand, if they do not "cross, at least to a slight extent, then they cannot "both be seen ahead. The real points to be studied in "fixing and arranging the inboard screens appear to "be, first, to ensure that the rays of the red and green "side lights do not cross each other immediately on "leaving the ship, nor at all more than is possible; "and secondly, to ensure that the distance ahead "within which neither light is seen is not greater than "can be avoided." Those are the original instructions to the surveyors for fitting screens. That practically meant, I presume, that the lights should be so screened that they would not cross the stem more coarsely than necessary. Then lately in 1892 an order was given to the surveyors that all screens were to be fitted to 4°, *i.e.*, set at an angle of 4°, so that the rays from the outer edge of the wick should cross the stem at an angle of 4° each side, and the shipping interests, the captains and owners, object to it as being too coarse a screening. The contention of the Board of Trade is that if you set the screen at 4°, and not less than that, two ships meeting each other will see when they bear 4° on each other's bows, for instance, both lights ahead or nearly ahead, and will port their helms according to the law and so cross one another's bows a little, but unmistakably, with port helm?—4° in my opinion is too much. You see electric bow lights at a great distance, and when there are a number of ships ahead, you may be endlessly running off your course, and getting into trouble when crossing the bow of a ship, of which you were already passing clear. I think 4° is too much.

5187. According to a calculation Mr. Bolam made, the Admiralty system would be 2½°. Do you see any objection to that being the practice?—No, I have not gone into the figures, but speaking practically I think it is a very fair working angle. I am quite opposed to having no angle, because otherwise in a very broad ship you would have a great dark lane for some distance ahead; it would not be very often, but it might so happen that a vessel whose line of keel was in the same line as that of another ship, might come within that dark lane without seeing her.

5188. Mr. Gray's verses, which we have heard, and which we do not use in the Navy: "Green to green, "red to red, perfect safety, go ahead," were made 23 years ago?—Yes, as far as I know.

5189. The Board of Trade rather contend that if you screen finer than 4°, two ships passing each other on parallel courses in opposite directions, bearing 2° or 3° on the bow of each other, will, if they see only the green light each continue their course and pass too close to one another, and perhaps come into collision. Do you see any reason, as a seaman, if you see a green light on your starboard hand why you should not give starboard helm, and give her a little more room instead of crossing her bows?—Certainly not, if you are at all in doubt, and especially if the light is seen nearly ahead.

5190. And considering those rules were made many years ago, when ships were very much slower than now, would it not be desirable that some alteration should be made so as to prevent unnecessarily crossing the bows at the much higher speed at which vessels now travel; where vessels now would come closer than they would when the rules were originally made?—I do not think you have any right to port if you see a green light on the starboard bow.

5191. No; but if you set those screens at 4° you will see both lights, and according to the law you would have to port although a vessel was 4° on your bow?—I thought you were speaking of seeing one light only.

5192. Yes, I was. Of course, if you see a green light only you would not cross the bows, but with a large angle of screening you would see not only that, but you would see both; if you were screened to 4° you would see both lights, and instead of being able to keep on your course on the side on which you saw the ship, you would, according to the law, have to port?—Well, I think with coarse screening in close quarters, such as in the Channel, you would be continually sheering away unnecessarily and possibly move from a position of safety to one of danger, by trying to cross to starboard where vessels were going at great speed, and the distance was misjudged.

5193. I merely put it as clearly as I can before you, because you have not heard what the discussion was about?—No, I have not heard about the particular point.

5194. Then you think 4° is quite an unnecessarily large degree of screening?—Certainly too much.

5195. (*Captain Barker.*) You say 2½° is about the angle at which the lights cross?—I accept the calculation made here. I would not like to pin myself to any number of degrees, because I have not gone into the matter. I take the distance arranged as far as I am concerned for any base (that is the 200 or 150 yards from stem).

5196. It seems to me that it would not be very difficult, with the regulation of the Board of Trade, of 4° from the outer edge of the wick, for the full light to be seen 200 yards ahead?—My belief is, at this distance of 200 yards, or 150 yards, as the case may be, the full light may be seen, but I know of no trials with a fixed angle of 4°.

5197. Then I suppose you get the ship against a dock, or something of that sort, to ascertain that?—Yes. It is usually done in our basins. If necessary the ship is moved so that these conditions can be practically tested, and are tested; and the ship is not accepted as fit for sea, or fit to pass over to the Executive Admiral, till the certificate is given that the lights have been tested and proved in place to fulfil the conditions laid down.

5198. Do you find any difference between the power of the two lights—do you find that the place where the full red light crosses the bow is different from the place where the full green light crosses the bow?—I cannot tell from practical experience. I have not tested the lights in that way myself.

5199. You have not noticed anything particular in testing the lights?—No.

5200. You have not noticed any difference in the power of the lights?—I can only judge with my own eyes, I always see a red light before I see a green one.

5201. I am supposing now you can walk down right from a position ahead of the ship, towards the ship, until you dim the lights; you would dim the green one sooner than the red, would you not?—I think so, but I have not tried it, excepting in making out lights ahead. I always see the red light before the green.

*Staff-Capt. Phillips.*

24 July 1895.

5202. But I do not know whether you found the full crossing point of the red light was different from the full crossing point of the green light; have you noticed that practically?—No, I have not, it has not been within my province to test the lights. I have talked with those who have and have got all the information from them, but it has not been within my province to to do it myself.

5203. (*Mr. Bolam.*) In the early days when there was no Board of Trade the Admiralty had full control of the question of side lights?—I cannot say about that.

5204. Are you conversant with the history of it?—No.

5205. You do not know anything about the sizes of of the wicks employed in these vessels, I suppose?—I can only tell you the size approximately, but I promised to send up specimens of the dockyard pattern wicks, and I will send you them up in a couple of days' time.

5206. (*Rear-Admiral Andoe.*) Have you got the specification there of the sizes?—Yes, of the lamps, and possibly they will give the sizes of the wicks.

5207. (*Chairman.*) There is one thing I am not able to understand. The Board of Trade Regulations with reference to the following are observed: "*a.* length of "screen; *b.* angle of light abaft the beam; *c.* Distance "ahead for both lights to be seen," but there is no Board of Trade Regulation about the distance ahead for both lights to be seen. That is not a matter that they take into consideration at all. I do not quite understand that?—No, this is a copy of the instruction for the Fleet, and Dockyard Reserve; they do give a distance there.

5208. They do, but I mean that the Board of Trade do not issue any order, or take any account of the distance. They regulate their screening by a totally different method, by taking the angle of 4° from the the outside of the wick, and before they used to regulate it by a line drawn either from the inside of the wick or the inside of the lens, not the distance at which the lights would cross. I do not quite understand how the Admiralty came to speak of the Board of Trade Regulations being observed. That is not a matter that the Board of Trade placed any reliance upon, unless they mean that their plan of fixing the crossing point is equivalent to the Board of Trade Regulation of 4°?—This was a practical description by the foreman of the shipyard who has charge of this particular work at Portsmouth, and I have just copied it out as he has sent it to me. I should say he made an error probably in using the words "Board of Trade." It may be "carrying "out the Admiralty orders as far as possible." No doubt he thought it was the Board of Trade.

Commander Noel called and examined.

*Commander Noel.*

5209. (*Chairman.*) Would you be kind enough to tell me your nautical experience. What office do you hold now?—I am commander for navigating duties. At present I am in the "Majestic," but I have been three years in the Channel fleet in the flag ship.

5210. As navigating officer?—Yes, previous to that I was second in command in the Anson.

5211. Have you navigated big ships?—Yes.

5212. Of the modern type?—Yes, the "Royal Sovereign" was my last ship. I was three years at sea in her.

5213. Have you been in vessels that have had the electric lights as well as those that have had oil lamps?—Yes.

5214. Recently? What is the last vessel you have been in which had the oil lights?—I think the "Iris" was the last ship I was in that had oil lights. That is about eight years ago.

5215. Was she a big vessel?—No, a 4,000 ton ship.

5216. A cruiser?—Yes, a cruiser.

5217. And she was fitted with oil lamps?—Yes.

5218. We have been told you do not use mineral oil in Her Majesty's ships?—No, we do not.

5219. How were her lanterns fixed—in a lantern box or something of that sort; do you happen to remember?—No, I do not.

5220. Whereabouts were they?—I think they were just under the fore bridge. That was about 60 or 70 feet from the bows.

5221. And you would not remember, I suppose, what the breadth of the wick was, that these lanterns carried?—No.

5222. They were certainly vegetable oil lamps?—Yes.

5223. Do you remember anything about the screening of the lights on that vessel. Were they screened with a screen and a chock; or how were they screened?—I could not say; it is too long ago.

5224. Then I should like, please, to come to the use of the electric light in the "Royal Sovereign." How was that carried—in a light turret, or how?—They were carried simply in an iron frame made to fit the lantern box with a small lid on top. You simply let the lantern down into it and put the lid on.

5225. Had you any apparatus for substituting oil in case the electric light went wrong?—Yes.

*Commander Noel.*

24 July 1895.

5226. Is that carried in the same box?—Yes, you take one out and put the other in.

5227. That, of course, would involve, whatever trouble there may be, in taking the one out and putting the other in?—Yes, so that they could light the lamps, and let them burn. They are kept close to, and ready so that it is only a matter of a moment lighting them, because the wicks are all ready.

5228. Those electric lights, did you ever happen to observe what number of filaments they had in the lamps; I suppose they were incandescent lamps?—Yes.

5229. How many lights were there; do you remember whether there was one incandescent light, or a group of lights?—I am not absolutely certain. I think there was only one burner with a single filament in it.

5230. Have you found in practice that the electric lights are liable to go out?—I have never known them go out.

5231. So that practically you think the electric light is a great improvement upon the former oil lamps?—Yes.

5232. You have no practical difficulty either in getting up the illumination or keeping it?—No.

5233. Do the lamps last a fairly long time; do you know if you often have to put in a new one?—I have never known the lamps to go out in that way.

5234. Now about the screening of these lights; have you noticed how that is effected?—There is a fore and aft screen, about three feet long, of iron, and the iron box—the circular iron box—contains the lantern and is made solid for about three inches. Then there is the glass, and the chock is placed on *here* so as to allow the light to show—it is roughly 3°—across the bows. It is done experimentally; they are placed at a distance of 200 yards (*describing*).

5235. That is supposed roughly to be about 3°?—Yes.

5236. That is the object which you desire to attain?—Yes.

5237. And for that purpose there is a chock brought to a certain point, which you say is determined by experiments?—Yes, it is done in the dock, and the man has two or three chocks and puts one a little thicker than another until he gets the right angle.

5238. It works out something like 3°?—I think about 3°.

5239. Now, I should like to have your opinion about this. I suppose you have not formed any opinion with reference to the actual angle of screening in that way?—No, nothing specially.

5240. But speaking more generally, what do you think as to the coarseness or fineness of screening; do you think it desirable that lights should be screened more finely?—More finely, I think.

5241. It is a practical question. You see the Board of Trade at present take the screening at 4°, and the view of a large number, at any rate, of the mercantile marine world is that 4° is too coarse, and they think it ought to be considerably finer. The view of the Board of Trade, as I understand it, is that if you have two vessels approaching 4° on one another's starboard bow, each would see both lights of the other, and under those circumstances they think it is a good thing that each should port their helms and cross each other's track. The view of a considerable number of persons engaged in practical navigation in the mercantile marine is that that is too coarse, and it would be better to have the screening finer, so that the vessels do not see both lights as much as 4°. As I understand you, your view rather inclines to a finer screening being the better?—Yes.

5242. One thing is put forward on behalf of the persons who think the broad screening desirable, namely, that supposing you were screened less than 4°, say 2°, each would see the green light of the other, and if each ship kept exactly the same course, 2° different, they would pass very close indeed or collide. One of the answers given by persons engaged in actually navigating vessels is that under those circumstances there would be no danger at all, because each vessel would naturally give a slight touch of the helm and so go sufficiently clear. May I ask you whether you take the view that there would be any position of danger supposing the vessels saw one another green to green under these circumstances, or whether you think the danger could naturally and easily be avoided by each vessel giving a touch of the starboard helm?—Well, I think vessels meeting as near as 2° would naturally port. 2° is practically right ahead.

5243. But I am taking the case of seeing the green light, of course you would not port to a green light alone?—Oh no; when the red is not seen?

5244. Yes, you see they are screened 2° and each vessel is 2° or perhaps more on the starboard side of the other?—Yes, I see.

5245. Each would see the green?—Yes.

5246. Under those circumstances do you think there would be any practical danger?—No, I do not think there would.

5247. Under those circumstances I suppose it would be natural, would it not, for each vessel to give a slight touch of starboard helm?—Yes.

5248. However slight it would secure their passing clear?—Yes.

5249. So that you see no reason to object to a screening as fine as 2°?—No, if you only see the green light the ship may be passing like *that*; the ship *here* naturally coming down would sheer off enough to clear the rest of the vessel.

5250. Of course it is obviously the duty of the man on the look-out and the people on the bridge, not only to act when they see a light, but to watch and see what it is doing?—Yes, undoubtedly.

5251. And if two vessels keep on approaching one another under those conditions, I suppose it would be clear to the mind of anybody that his duty would be to give a slight touch of starboard helm?—Yes.

5252. (*Rear-Admiral Andoe.*) This law was made originally for passing ships, more than 23 years ago when ships were much slower than they are now; the fact that ships travel much faster now would, I suppose, strengthen your opinion in favour of finer screening. Vessels approaching one another at 15 or 16 knots each, each 4° on the other's starboard bow, have at present to port their helms and cross one another's bows?—Yes, I think that would make a ship uncertain. Well, if there is such a large range across the bow, I think it would make an approaching ship uncertain what to do.

5253. Of course the law lays down that if you see both lights at once nearly ahead you are bound to port your helm, that is clear?—Yes.

5254. With a 4° angle, whether you think it necessary or not, when you see both lights you must port your helm to keep within the law?—Yes.

5255. But in many cases would it not be unnecessary to port the helm at all if you continued your course and gave a little starboard helm; supposing you did not see both lights there would not be the necessity to cross the bow?—You may have to port and traverse in only two miles something like 400 yards.

5256. I believe we have not altered the angle of screening in the Navy, we still screen as formerly, but in the merchant service they now set their screens to 4°?—Yes.

5257. And the mercantile marine take exception to it, and consider that too coarse an angle because it makes them cross the bow unnecessarily?—Yes.

5258. Is it quite clear to your mind that it is unnecessary to cross the bow at that angle?—Yes.

5259. (*Captain Castle.*) I think I understood you to say that seeing a green light a little on the starboard bow you would starboard only if you thought you were getting too close?—Yes.

5260. (*Captain Hallett.*) Can you tell me what the diameter of the "Royal Sovereign's" tactical circle was?—660 yards.

5261. That is the diameter of the circle in which she turns?—Yes.

5262. At what speed was that, can you remember?—Well, that was done at 12 knots; but it varies very little.

5263. Can you remember in the early part of the circle how far she went for the first quarter?—How far ahead?

5264. How far ahead, and how much transfer, and how much the advance was?—Well, the advance was roughly 500 yards.

5265. In the first quarter?—Yes.

5266. Can you tell me what the transfer was roughly?—No.

5267. (*Rear-Admiral Andoe.*) I suppose about a third of the radius?—Yes.

5268. (*Captain Hallett.*) I did not know whether you remembered it or not. What is her beam?—75 feet.

5269. Have you, steaming at night in close order with a similar ship astern of you, ever been able to find a dark lane—that is where you could not see either of the next ship's bow lights? What was the closest distance you have been at night in that way?—I dare say 50 or 60 yards.

5270. And you have never found yourself in a position where you were in what is called a "dark lane"?—No, I have never seen it; but I will not be absolutely certain.

*Commander Noel.*

24 July 1895.

5271. But in your experience you have never seen it?—No.

5272. Although you have been both on the bridge and in the after part as well?—Oh yes, right aft.

5273. Which makes a great deal of difference in the length?—Yes.

5274. You have never experienced that?—I have never seen it, no.

5275. (*Mr. Bolam.*) Do you know the width of the wicks at right angles to the keel in any of the ships you have been in?—I am afraid I do not.

5276. Or what was the width of the filament in the electric light, from outside to inside?—No; it depends, I think, upon the way it is put in.

5277. You do not know it?—No, I do not.

---

## Thursday, 1st August 1895.

PRESENT:

THE RIGHT HON. SIR FRANCIS H. JEUNE IN THE CHAIR.

| | |
|---|---|
| Rear-Admiral ANDOE. | Captain HALLETT. |
| Captain BARKER. | Sir E. HARLAND. |
| Mr. BOLAM. | Mr. SCRUTTON. |

Mr. C. HIPWOOD, *Secretary.*

Staff-Commander EDWARDS called and examined.

*Staff-Commander Edwards.*

1 Aug. 1895.

5278. (*Sir E. Harland.*) [*In the absence of the Chairman.*] I believe you have been at sea a good deal?—I have.

5279. And have you settled down to some post on shore?—I have not yet.

5280. So that you are not in a position specially to superintend or to watch the question of the screening of lamps?—At present no, I am not; I retire on Saturday; then I shall be.

5281. I should like to ask as to your experience at sea with reference to the character of the red and green lights; have you found the lights supplied pretty uniform in their strength?—Very.

5282. And in the character of the light?—Very.

5283. Have you found that they were, so far as you are able to judge, pretty accurately screened?—They are all tested and actually tried before the ship passes into the Fleet Reserve.

5284. Were you aware of the angle at which your lamps were screened?—I can tell you what they were by working them out, otherwise no. They cross at 150 to 200 yards according to the regulations and are actually tested.

5285. That is to say that the lights were open at 150 to 200 yards ahead of the vessel?—Yes, depending upon the beam of the vessel.

5286–7. (*Chairman.*) You were telling the Committee the present rule, I gathered, which regulates the screening in the navy?—Yes.

5288. What seems to govern their view is the distance ahead of the ship at which the lights cross?—Yes.

5289. And that has always been the way in which they have had them?—They actually test them at night; we get them in the dock, measure the distance and actually screen them to that; we put fillets on the end of the screens where necessary and each ship in the dockyard is tested before it is allowed to go into the Fleet Reserve.

5290. Do you have a check on your screen?—Yes, some of them, those that need them; on those that do not, of course, we do not put the check.

5291. You are aware, I suppose, of the rule the Board of Trade requiring lights to be screened to 4°?—Yes.

5292. The Admiralty have as a matter of fact made no alteration in their practice from what it was before 1893?—They have not.

5293. I do not know whether the Admiralty consider that the 4° angle of screening is right, or whether they abstained from adopting it because they thought it unnecessary?—I do not know; we simply have kept to the same rule as we had before 1892. They cross at 200 yards for a large ship, and 150 for smaller vessels; it depends upon the distance between the two lights.

5294. Have you yourself considered this rule of the Board of Trade of screening to 4° from the outer edge of the wick?—I have only taken a cursory glance at the rule; I have never gone into the matter of the 4° screening. It strikes me that at the end of the two miles distance, the shortest limit at which the lights should be seen, the base is much too large; in fact a great deal too large.

5295. I wish to have the value of your opinion upon the question as to whether you consider 4° unnecessarily large?—I do certainly.

5296. Do you see any danger at all in having a finer dégree of screening than 4°?—No, I think it would be matter of safety—I think it would be safer. Of course, making it a smaller angle would reduce the base at that distance of two miles, so that we have not so much transfer with the ships meeting end on; for instance, take the case of two ships meeting nearly end on, each on the other's starboard bow; if each was just within the other's three lights they would have a long distance to cross to the other side, in obeying the rule which tells them to port, if the three lights are seen nearly ahead; therefore, if you lessen that distance he would not have so far to go.

5297. You do not see any reason for having so broad a base?—No, it is unnecessarily large, more especially with long ships going at great speed as they do now.

5298. The greater the speed the more risk there is of collison, if crossing has to be done?—Yes, and the less time there is to see the light; and every second is of

*Staff-Commander Edwards.*

1 Aug. 1895.

importance to a man when he looks at a light, and has to decide what action he will take.

5299. Are the lights used by the Admiralty usually placed as in merchant ships, or in turrets?—It depends entirely upon what a ship is like. It is almost always different; in old ships they have them let into the bulwarks of the ship itself; others have simply a screen put on top of the gunwale and others have a screen under the bridge; it depends upon the arming of the ship, everything has to be sacrificed to the arming of the ship. You give them an uninterrupted light, but of course if there are guns or torpedoes, or anything of that kind in the way, lights must go elsewhere. Knowing that I was coming here I got a list* of a lot of the different types of ships we have, to show the distance between their lights; for instance, the "Hussar" a torpedo destroyer, the distance between the lights is 23·3 and the distance of the light from the stem is 68·3. The "Agamemnon" is only a few inches more and 138 feet from the stem; the lights are on a bridge which passes round the funnel, therefore they increase the base of that very little. In another ship, the "Belleisle," whose beam is not so much, the distance between the lights is 49 feet, more than double. It all depends upon the guns and armaments.

5300. As a rule you do not seem to put them at the end of the ship or anything like it?—You cannot do it in turret ships, because they are all so low. As I said, the type of the ship, and the guns, and the armament, have to be considered first now. After they have completed the ship, then they put the lights in.

5300*a*. (*Mr. Bolam.*) Will you ask the witness, sir, whether in the case of the "Agamemnon" the lights cross at 200 yards.

5301. (*Chairman.*) That is the very question I was going to ask. When you say the lights cross at 200 yards ahead, what do you take as the mean distance between the two lights?—We take whatever the distance may be; we converge the lights to that, and allow the screen to suit that.

5302. Whatever the distance may be between the lights, you make them all cross at from 150 to 200 yards ahead?—The lights are put in after the ships are completed so far as the dockyard is concerned. In the dockyard there is a distance measured on the shore on purpose for the lights, and if you find the lights are too much open the angle is altered so as to make the lights cross at the proper distance by putting a fillet on at the end of the screen. We actually make them cross at that point; no matter what the beam of the ship is, they have to cross at that particular point. At the crossing point we see the light full, and then as we walk towards the bows, the light gradually disappears, till I think about 60 yards from the stem of the ship it is all darkness.

5303. (*Mr. Bolam.*) Then that ship's lights could not cross 200 yards ahead of the ship?—Oh, yes; they are all made to cross there.

5304. So that you have a half base of nearly 12 feet to the perpendicular of 600 feet?—Yes.

5305. (*Chairman.*) Is the 200 yards measured from the lights, or from the stem of the ship?—From the lights, the base of the lights, because the "Agamemnon's" lights are far aft, but they are on the bows in the other cases.

(*Chairman.*) What would that work out at, Mr. Bolam?

(*Mr. Bolam.*) That works out at 1° 5′.

5306. (*Chairman.*) I wanted to ask you something about the electric light; that is used a great deal in Her Majesty's ships?—The newer type of ship would use it.

5307. Have you had any practical experience of electric side lights?—No, I have not; I have seen them in other ships.

5308. I wanted to know what breadth of filament, and what candle-power is usually used?—I could not tell you; I have never beeen in a ship with electric bow-lights.

5309. You have not seen them fitted?—No: I have only seen them when we have been manœuvring.

5310. You have never looked at them carefully?—No.

5311. Do they work very well?—Fairly well?—We always use the precaution of keeping other lights ready; in many ships we keep them ready lighted to put in at once. My ship uses the old lights as usual.

5312. Do you know if any complaints are made about them?—I have heard of none, not a single complaint; they are getting on very well.

5313. The oil lights do not burn mineral oil?—Colza oil is used in Her Majesty's ships.

5314. Do you know at all the breadth of wick they use?—An inch and a quarter; a 4-inch wick is an inch and a quarter wide, and the height of the base of that at the top of the wick where the light is 6½ inches.

5315. I see Captain Phillips has been kind enough to send us specimens. I suppose those are the wicks (*produced and shown to the witness*)?—Yes.

5316. And he has kindly sent us a drawing showing the way they are placed. That is the way they are placed, I think (*handing the drawing to the witness*)?—Yes.

(*Mr. Bolam.*) It is placed so as to have the smallest possible transverse wick.

5317. (*Chairman.*) So that they do not really represent a wick an inch and a quarter wide, because they are put sideways?—That is so.

5318. Something about an inch or so?—Something about that.

5319. (*Rear-Admiral Andoe.*) Did you observe in the squadrons cruising that the electric light was too strong?—I have never cruised with the electric light.

5320. You have never noticed it in other ships?—No; the other day I saw a mail-boat going out, and I did not think it was too strong at all. I think it is a great advantage to see a light at a greater distance. It gives one more time, especially if it happens to be misty. There is only one thing I wish to mention—about the masthead lights—they carry them too high in misty weather.

5321. Do you mean the electric light or ordinary lights?—Both. You cannot see them above the lower masthead. You can see them to that height, but not above it.

5322. The regulation says that they should not be lower than the distance between the two lights?—Yes, they can go any height above the regulation height, and in misty weather they ought to lower them below the lower masthead.

5323. What do you think should be the distance?—The old distance, about the beam of the ship, but not under 20 feet.

5324. In misty weather they lower them down a bit?—Yes, they ought to; but in fine weather carry them up; you can then see the light looking just like a star rising, perhaps 8 or 9 miles off, and as you get nearer you gradually see the bow lights, but in misty weather you would not see the masthead light, if kept as high.

5325. It would be better that it should be lower down in misty weather?—Yes.

5326. You know the Board of Trade officials contend that screening 4° gives vessels meeting one another in opposite directions, a little on each other's bows, but on parallel courses, a better opportunity of porting and crossing one another at a safe distance; and the idea is that if there were fine screening one might possibly port, and the other might starboard. What is your opinion upon that point? Have you given that any consideration?—If they would port in the first case, surely they would port in the second. The only objection, I think, in the first case is too large a base. For instance, if I saw the three lights on my starboard bow, and I just saw the red at this 4° angle, I should have a much larger space to go across, and if I was going as we do now, 15 or 20 knots, with a long ship, I have a very good chance of getting into collision.

5327. Even though both are reported at the same moment?—Yes, and you may not see them quite at two miles, and you do not act at once; for instance, I take it your ship might travel on 200 or 300 yards before she would alter; you must always take that into consideration, and the speed of long ships.

5328. Then you think crossing the bows is objectionable?—Yes, for instance, if the 4° was reduced to 2° I should not touch my helm at all, I should go straight on, as I would not then see all three lights of the other vessel.

* *See* Appendix 15, No. 1.

5329. Then you can always give starboard helm, and give more room. If you thought you were going too close, you would naturally alter or keep more on the side you found yourself on, and give more room?—Yes.

5330. There is another thing in fine screening—does it not occur to you that the ship more clearly indicates any change in her course?—Yes, at once.

5331. And that is not the same with a larger angle of screening?—No, as you keep on longer, you go further out of your course necessarily.

5332. (*Captain Hallett.*) Did you ever serve in a flagship of a squadron?—No.

5333. You have served in big ships, I dare say, in a squadron?—Oh, yes.

5334. Have you ever in the line ahead lost sight of both lights astern of you?—Never.

5335. Have you been in close quarters?—Yes.

5336. And you have never found yourself in such a position that you could not see both or one of the lights?—I could see both lights always, except at about 60 yards. I have never been so close as that. It is the distance you test them in the dockyard before they are turned out ready for sea. The last thing you try is the lights, and you get into this dark lane about 60 yards from the stem of the ship. It depends upon where your lights are.

5337. That is from light to light?—No, if you have the crossing point at 200 yards, and then walk in they will disappear at about 60 yards.

5338. You are talking of when you are in position on the bridge probably—the distance of 60 yards that you speak of would be the distance from light to light?—The distance from where I am to the lights when I lose them is about 60 yards.

5339. But you have never found yourself actually in the dark lane?—Never. I have never lost sight of both lights crusing with the squadron.

5340. (*Captain Barker.*) In marking the position of these lights where they cross, do you walk towards the ship or from the ship, or can you observe them both ways?—Both ways. The thing is actually measured with a line, and there is a mark put down, and then when you get to 200 yards you see the lights shining fully bright, and as you walk in they get dimmer. As a rule we lose sight of them at about 60 yards distant.

5341. Do you find any difference in the dimming of the lights, or are they about the same?—They are fairly equal.

5342. (*Mr. Bolam.*) Have you any idea of what this angle of 1° really means. Is it an angle at which the light from the inside of the wick crosses the fore-and-aft line of the ship or from the middle, or the outside?—Right off the centre of the wick.

5343. Then you think this 1° really means from the middle of the wick?—Yes.

5344. (*Sir. E. Harland.*) I scarcely heard you distinctly with reference to the line of the lights crossing at 200 yards ahead of the light. Is that irrespective of what the distance might be between the red and green lights in a ship?—We make that the distance in crossing.

5345. And have you any instance of where the lights would be, say 70 or 75 feet apart?—Oh, we have all the bigger ships, the first-class battleships, such as the "Empress of India," and the "Royal Sovereign,"—all these new ships of 14,000 tons are of 75 feet beam. Then I take it their lights are 70 or 75 feet apart.

5346. And in these vessels with the lights 70 feet apart, would the lights be screened so that the direct light from each would cross at 200 yards ahead?—Certainly.

5347. Then what angle do you conceive that would give?—This angle is 3° 26′, but then that gives us a base of over two cables.

5348. Is it not more than 3° 26′?—No, 72 feet between the lights at 200 yards is 3° 26′;* reckoning from the centre of the lights, from light to light—3½° practically.

5349. (*Rear-Admiral Archer.*) Does that mean the two lights at this angle?—Is that the whole or half length?—That is the angle at which the light converges to the fore-and-aft line.

5350. To the fore-and-aft line?—Yes.

5351. (*Sir E. Harland.*) Assuming that *this* is the bow of the ship, and *that* is the position of the light *there*, and the position *here* in this triangle is 72 feet, then at 200 yards ahead they will cross?—Yes.

5352. And that will be the direct light from the wick?—Yes, not the reflection.

5353. If such be the rule in the navy with 72 feet between the lights, what would be the rule if there is only 36 feet between them?—At 36 feet they would cross at 1° 36′.

5354. Is that the practice still?—That is the practice. That is what we do with all ships, even the "Spider," which is only 12-feet beam; we took it at 150 yards.

5355. But you would not reduce it in vessels half that beam, 36 feet?—No.

5356. Are you aware that that practice in the Navy is very different to the practice in the Mercantile Marine?—I do not know the practice in the Mercantile Marine.

5357. (*Chairman.*) Is that from the centre of the wick?—Yes.

5358. (*Mr. Bolam.*) They call it the full light; that is the puzzle?—Yes, so it is. When we test our lights we always take a fine dark night, and the ship is placed in position, and the distances are all measured. We go out that distance, and then we walk in.

5359-60. (*Sir E. Harland.*) Then you have not perhaps followed the report in the papers of the views which have been taken by the Mercantile Marine with reference to the screening of side lights?—No, I have not seen them.

5361. Do you approve of this plan of the angle of screening varying with the beam of the ship?—I do. I think the base upon which we should all work should be the base of the triangle at the other end, the breadth over which the three light show at 2 miles, and I think a cable would be ample for this distance.

5362. What would your opinion be for practical purposes as to a uniform angle for screening, irrespective of the beam of the ship?—I do not quite understand your question.

5363. Would you prefer to adhere to the plan in the Navy, or to have one uniform angle irrespective of the beam of the ship?—I would not have a uniform angle; it would be impossible to give it in our ships, because we are obliged to put them in so many different positions.

5364. But could you not regulate that by the angle of the screens?—I do not quite follow you.

5365. Could you not make it anything you choose by putting a chock at the end of the screen?—I could not work upon that basis at all.

5366. Are you aware that that is the rule at the present time which is followed by the Board of Trade; a certain angle is determined upon, quite irrespective of the beam of the ship?—I do not know; we have never practised it. The orders are to screen so that the lights cross at from 200 to 150 yards.

5367. In approving of the practice of the Admiralty do you see that it pays no regard whatever to the width of the field. Here is a vessel, and at a certain angle the green light opens out on the port side and at the same angle the red light opens out on the starboard side. Are you aware that in a vessel of double the beam the field would be at once doubled?—Yes, quite so.

5368. Do you think that the width of the field should not be considered?—No, I would fix the width of the field at one cable and work from that.

5369. Are you aware that if you followed that out, you would then, practically speaking, have to screen your lights to a certain angle, almost irrespective of the beam of the ship?—I would have to do that. I do that every day. We have so many ships of different types.

5370. But your statement just now to us was that you preferred to adhere to the lights crossing each other at 200 yards ahead irrespective of the beam?—I do not prefer that; I think you misunderstood me; that is no preference of mine. We cross them according to the order.

5371-2. Then you say the rule is even in large ships in the Navy for the lights to cross at that fixed point?—Quite so.

* See Appendix IX, No. 2.

*Staff-Commander Edwards.*

1 Aug. 1895.

5373. And I understand you to say that that plan is adopted quite irrespective of the beam of the ship?—Except in small ships.

5374. Take the large ships irrespective of whether the beam of the ship is 40 or 70 feet?—Yes.

5375. If that be the test then would not that at once have the effect of rendering the breadth of this field at 2 miles totally different for different ships?—Yes.

5376. Depending entirely upon the distance apart?—Yes, we will take a ship with 36-feet beam, and another with 72, the 72-feet beam ship has double the base that of the 36-feet beam ship.

5377. Then do you prefer that that base should be uniform?—It should be uniform.

5378. Then if you prefer that, does it not necessarily follow that you must abandon this principle of 200 yards?—Certainly I should like that taken away. I do not want that; I want to take my base line of one cable at 2 miles distant as the standard, and work back to the ship.

5379. Then you do not approve of the present custom?—I do not; it makes the base too large altogether.

5380. Then with reference to wicks, do you think the Admiralty plan is the best way of placing them? Do you think it preferable to place those wicks at different angles, instead of, as is customary in the Mercantile Marine, placing one wick immediately behind the other one, parallel?—I never tested them; I could not say it was preferable. It may give a better light, or it may not; I am not prepared to say which way that is, but I take it that would be the result of the experience of somebody else.

5381. Is that the invariable custom?—Yes, that is the invariable custom.

5382. Do you make any difference between the intensity of the light applied to the green shade or the red shade?—They are exactly the same.

5383. And I think you observed no difference in the intensity of the lights?—It gradually disappears as we walk towards the bows.

5384. You would not consider the green light any weaker at 2 miles than the red light?—No, certainly not; it is perfectly discernible—the green from the red—there is no mistaking them one for the other.

5385. But would you lose the green sooner than the red; if the red was fairly bright at 3 miles distance, do you think the green would show as strongly?—No, I think the green in all cases would get dimmer before the red.

5386. Have you ever in the Admiralty adopted the practice of having a duplex wick for the green light and a single wick for the red?—No, they are exactly the same.

5387. All the wicks are the same size?—All the lamps are the same size. You can take the lights from the "Spider" and put them into any other ship of the navy.

5388. You have one standard power?—Yes.

5389. And that applies to all vessels?—Yes.

5390. Does that apply to the masthead light?—Yes, they are all the same. You can take the wick out of one lamp and put it into another.

5391. Are there many of your vessels lighted by the electric light?—Some of the newer ones are, but I could not tell you anything about them from practical experience, except that they seem very bright but not too bright. I think the brighter they are the better.

5392. Has it occurred to you in your nautical experience that the angle of screening should be finer or coarser than in practice it would appear to be in the Navy?—I would start from the base of one cable at 2 miles distant, which would make the screening finer. With the present screening in Her Majesty's ships it gives us a base over 2 cables, which is too much, I think.

5393. What is your opinion of screening perfectly parallel with the light, for the light strictly speaking not to cross the centre line at all?—I would rather have them cross a little. I would not have them simply show green on the starboard side and red on the other, and not see them cross at all.

5394. At what distance ahead would you propose that they should cross as against the 200 yards, if you had your own choice in the matter?—Well, you see I start my base of one cable about two miles distant, which I think a very fair one; if you did not see the lights at that distance, and you were steaming at 20 knots, and meeting end on, it would be almost hopeless.

5395. Supposing you saw it at 1 mile distance, what do you think about that?—Yes, I think that might possibly be sufficient. I should not like it less.

5396. (*Captain Hallett.*) You say you take a cable as your base, from what?—At 2 miles distant.

5397. (*Sir E. Harland.*) Then, in place of the lights crossing at 200 yards ahead, you would prefer them to cross really at 2,000 yards, which is a mile ahead?—Well, if you have a fixed crossing point I can have no fixed base at the other end (2 miles distant); it will vary with the distance the lights are apart; if you make me cross at 200 yards and those lights are 70 feet apart, you make my base over 2 cables, which I consider much too large.

5398. (*Mr. Bolam.*) The whole breadth is one cable?—Yes.

5399. (*Captain Hallett.*) Not a cable either side?—No, that is too much. We have half a cable on either side, that is quite enough, but I would reduce that if I could. My object would be that a touch of the helm should clear the ships, but if I have a broader field, I have a longer distance to run (*explaining with diagram*).

5400. That is to say, you wish to leave the field here a certain width, in which you may be free to see both lights of the approaching vessel?—Yes, at two miles' distance, to be one cable broad.

5401. And you limit that considerably compared to what the Admiralty do?—A half, or less than half.

5402. (*Rear-Admiral Andoe.*) Supposing you take the base at two miles as you say, the consequence would be that the screens of all ships not could be set at the same angle?—Oh, no.

5403. They would all have to be set at different angles?—Every one, varying with the distance between the lights.

5404. Therefore in merchant ships it would be almost impracticable to do it?—I take it you could have your 3-feet screens, and do as we do, alter the angle by putting fillets to cut the light off.

5405. But you could not do it by experiment in the docks—it would be impossible. It would all have to be theoretical?—Yes, we do it theoretically now; if you take the base at two miles to be one cable, the angle of convergence could be easily worked out, and would vary with the distance between the lights.

5406. I quite see the theory, but the difficulty in my mind is, that you would have to set the screens all at different angles?—There would be no difficulty. You could have a table. I want to leave the ship out of the question altogether.

5407. To bring that about the screens would have to be set in proportion to the distance between the lights?—Yes; then you can work it out. You can have different tables. If it was 12 feet it would be so much, and if it was 14 feet it would be so much, and if it was 30 feet it would be so much, and so on.

5408. (*Sir E. Harland.*) Then this plan just illustrates the objection you have?—Yes.

5409. At this distance from the approaching vessel, the field *here* varies considerably?—Yes, it is much too large.

5410. In one case it is much too large, and perhaps in this case you would say it is too small (*referring to the diagram*)?—Oh, no.

5411. Therefore your remark just now is in favour of very fine screening?—Yes, certainly; I start with a cable at two miles' distance—I think that is a very fair distance.

5412. (*Mr. Bolam.*) With regard to the cable as the width of the field, would you kindly say whether the amount of light that would satisfy you would be 1° 25′, supposing it is that from the middle of the wick?—Yes.

5413. Then it will be less than that from the inside?—Yes, we work always from the centre.

Staff-Commander GEORGE S. KEIGWIN called and examined.

*Staff-Commander G. S. Keigwin.*

1 Aug 1895.

5414. (*Chairman.*) Would you tell me what your present occupation is?—I am attached to the Royal Naval Barracks at Devonport.

5415. What experience have you had at sea?—My last ship was the "Anson" in the Channel squadron. I was staff-commander of her.

5416. And you have had experience in other ships, I dare say?—In the "Orontes."

5417. They are both large vessels, I believe;—Yes, the "Anson" is much larger—she is a battle-ship.

5418. She is one of the first-class battle-ships?—Yes.

5419. We want to ask you about this question of screening the lights. As I understand the Admiralty decide the angle of the lights by seeing that they cross at a certain distance according to the breadth of the vessel's beam, varying from 200 to 150 yards?—Yes.

5420. I do not want to trouble you about all the details of that, because we have heard about it from one or two of the witnesses; but what is your view about fine screening and broad screening? You know that the Admiralty practice seems to be different from the practice in the merchant service under the new rule—I dare say you know the new rule of the Board of Trade, which prescribes 4° from the outside edge of the wick?—Yes.

5421. Have you formed any opinion as to whether that is unnecessarily coarse?—Well, I should think it was. I have found, so far as our own ships are concerned, that the lights seem to be very well screened. I know that a similar ship, the "Rodney," was often astern of the "Anson" in the line, and the instant she altered her course she shut the lights out.

5422. Are the "Rodney's" lights screened the same as yours?—Yes, they are all the same.

5423. Can you tell me approximately the breadth of beam of the "Anson"?—The ship is 68 feet broad, and I should think between the lights the distance is a good deal over 60 feet, probably about 64 feet.

5424. Do you know where her lights are?—They are all in the same position immediately under the fore bridge.

5425. Were they screened?—Screened with a board.

5426. And we understand that in those vessels they are screened so as to cross at 200 yards from the light?—Yes.

5427. You say you have had the "Rodney" following you in a line?—Yes.

5428. I suppose you never noticed any difficulty arising from a dark lane? You have never been so close as to lose sight of her lights altogether, have you?—No, I do not remember noticing it, because sometimes she came up too close they would give her yaw out of the line, when the off light would immediately disappear the other remaining in sight.

5429. If they did that they would not come right astern?—No.

5430. And there you found the lights did, as the vessel changed her course; show very quickly?—Yes.

5431. And have you formed any opinion as to whether or no you saw very much of both lights, or whether a very small alteration gave you sight of one or the other. I mean whether she seemed to be screened fine or coarse?—There was a slight dimness at first, then you would lose it, but it seemed to alter very quickly.

5432. Was that the electric light or an oil light?—The electric light.

5433. Do you find the electric light work well?—We never had any trouble with it the three years I was in her.

5434. It did not go out or do odd things of that kind?—No.

5435. I suppose you always keep the oil lights ready in case of emergency?—Yes.

5436. But you did not have to use them?—No.

5437. Did you notice the breadth of the filament of the electric light?—No, I did not.

5438. Or the number of filaments?—No.

5439. Nor perhaps the candle-power either*?—No.

5440–1. Of course the electric lights in the "Rodney," for instance, are very powerful?—Yes.

5442. The masthead light of the "Rodney," I suppose, is an electric light too?—Yes.

5443. Did you notice whether the masthead was so powerful as to dim the other lights at all?—No.

5444. Because we found the other day when we were experimenting that if you had a very powerful masthead light it did dim the side-lights?—Yes, it might sometimes. I have found at times that it is very difficult in passing merchant ships to pick out the green light, what with so many saloon lights and that in the neighbourhood; but I never noticed it with our ships.

5445. With regard to the question of fine or wide screening, is it your view that the screening should be as fine as may be, or that it should be somewhat broad?—I think myself the finer you can get it the better.

5446. You do not see any danger that is likely to arise if the lights are screened fine?—No, I do not.

5447. The suggestion made by persons in favour of broader screening is that if they are screened fine you may get a position in which, if the vessels are on exactly parallel courses, each slightly on the starboard bow of the other, if they were to keep their courses exactly, they would almost if not quite touch; it is suggested, therefore, that the screening should be broader, so that under those circumstances they would each port their helm and cross. Do you think that is a practical thing?—The position in which you place them then is very liable to cause danger; if you could depend upon both porting at once it might be done, but with these heavy ships going at a high rate of speed, if one ports and the other does not, I should think a collision would be inevitable.

5448. So that you would prefer them to keep their own courses on that side upon which they found themselves, and I suppose, if necessary, you would prefer a touch of starboard helm to keep clear?—I should not prefer a touch of the starboard helm.

5449. You would rather they kept their courses?—Yes, but I think all fineness in the steering should be discouraged as much as possible.

5450. You do not prefer that they should pass each other too close?—No.

5451. Supposing two vessels like *that* and each saw the other approaching like *that*, the lights not being exactly in the same bearing, something like a quarter of a point, do you say under those circumstances you would not recommend that each should give a slight touch of the starboard helm, or what would you recommend them to do [*describing*]?—I think the only safe thing if the ships are nearly ahead is to obey the existing rule.

5452. Not quite ahead?—Or very nearly. Of course, is it very difficult to say which way the other ship will go for the moment; it is a momentary thing. Of course, if you had a broad course you would have more room, but if you have a fine course you would not; then I think they should follow the existing rules.

5453. (*Rear-Admiral Andoe.*) Do I understand you to say you would not, although you were going to pass very close to each other, green light to green light, starboard your helm, or would you sooner run a risk of a very close shave?—I do not believe in a very close shave at all, but I do not think it right to allow the option of the starboard helm, that is to say, to lay down the law.

5453*a*. So as to make it imperative?—Yes.

5454. Supposing two ships very finely screened were approaching each other a quarter of a point on each other's starboard bow; you see one another's green light ahead, or nearly so. If you both continue your courses you must make a very close shave; you are not

* Staff-Commander Keigwin subsequently wrote to say that the lamps were of the ordinary incandescent type consisting of a pear-shaped filament with one loop at the upper end, and were of 16 to 20 candle-power.

*Staff-Commander G. S. Keigwin.*

1 Aug. 1895.

justified in crossing the bows unless you see the red as well as the green, are you?—Exactly.

5455. Therefore to keep clear of each other you would each give a touch of the starboard helm to increase it?—If only the green is showing I have been assuming in answering the previous questions that all three lights were in sight, and what I meant to say was that the helm should not be allowed to be put to starboard as long as all three lights are in sight. Consequently the finer the screening the more time and room there is for the ships to port and pass on their proper sides; when, however, the red light is shut out there can be no objection to starboarding, if necessary, to give more room.

5456. Green to green?—Yes, certainly, so long as you do not see the three lights.

5457. But directly you see the three lights the law is what?—To port your helm.

5458. Both of you?—Yes, to my mind that is where the safety lies.

5459. The Board of Trade's contention is that with the lights crossing at the 4° angle the two ships would see each other's green lights in good time so as to port their helms and go clear of each other by crossing each other's bows. What is your view of that?—Well, I cannot help thinking that if a ship sees the three lights she ought to pass on the port side of the other.

5460. Quite so, that is the law; but is it desirable that you should make the lights cross so much as to have a large base?—Oh no, certainly not, that is why I think the fine screening better.

5461. Do you consider the 4° angle is too coarse?—Too coarse.

5462. You think so?—Yes.

---

## Wednesday, August 7, 1895.

*Mr. H. E. Deadman.*

7 Aug. 1895.

PRESENT:

THE RIGHT HON. SIR FRANCIS H. JEUNE IN THE CHAIR.

Rear-Admiral ANDOE.
Captain WILSON BARKER.
Mr. BOLAM.
Captain HALLETT.
Sir EDWARD HARLAND.
Mr. C. HIPWOOD, *Secretary.*

Mr. HENRY EDWARD DEADMAN called and examined.

5463. (*Chairman.*) You are connected with construction at the Admiralty, are you not?—Yes.

5464. Will you kindly tell me exactly what is the position you hold?—I am a Chief Constructor.

5465. Where?—At the Admiralty, in the Constructive Department; Assistant to the Director of Naval Construction.

5466. Where are you stationed?—At the Admiralty now.

5467. What are your duties so far as regards construction in respect to ships' lights. What have you to do with the construction of them?—In my present position I have no special duties except as regards examination of and reporting upon proposals for the position and mode of fitting of lights that may come from the dockyards or from the contract yards.

5468. Do you mean the position of lights in the vessels?—Yes.

5469. Does that include placing them in turrets, and so on, or is that simply as to the position of the lamps?—I am speaking now of side-lights; the position of lights on the ships.

5470. Does that include the placing them in the turret, or as to the construction of the turret, and so on?—You refer to what we call the lamp box. We have no such thing in the Navy as a turret or lighthouse. The lamps are fitted in boxes.

5471. Then, one thing you have to do with, at any rate, is the position of the lamps in the ship; that is to say, how far forward and aft they should be placed?—Yes.

5472. I suppose that has to be determined, has it not, by the nature of the ship?—That has to be determined by the nature of the ship, and the surrounding fittings.

5473. And, of course, you have to subordinate the position of the lamp to the position of the guns, and so on?—Just so.

5474. Now, generally, whereabouts in regard to amidships are lamps placed. Do you place them forward generally of amidships, or about amidships?—Not amidships, certainly, generally as near as possible abreast of the foremast, or the position where the masthead light is placed. That is one point we keep in view, so as to have all the lights as nearly as possible in the same athwartship plane. As a matter of fact, I should say, generally we put them rather forward of the foremast or position of masthead light.

5475. Are they carried at the extreme breadth of the ship, wherever they are placed?—Yes, they are carried at the extreme breadth of the ship, at the spot where they are placed, but not necessarily at the extreme beam of the ship.

5476. Have you anything to do with the construction of the lamps, or with the construction of the lamp boxes?—The lamp box, not of the lamp. There is a standard pattern Admiralty lamp, of course, which is used.

5477. You have to do with the lamp boxes?—I have to do with the lamp boxes.

5478. I do not quite understand, I am afraid, exactly what a lamp box is. What is the sort of thing that is used?—I have with me a copy of the Admiralty Instructions. They are very concise, accompanied by a sketch which shows the kind of thing which is referred to as the lamp box (*produced*). It is just simply a box suitably placed to contain a lamp.

5479. Does that apply even in the case of electric lights?—Yes.

5480. You only use vegetable oil, you do not use mineral oil?—No.

5481. But you do use electric lights?—Yes, in all ships which have electric light installation for lighting the ship; the bow lights are also lighted by electricity.

5482. So far as your experience goes, do you find the electric light works very well?—Yes, very well. We have no trouble whatever.

5483. Do you know the power of electric lights which is adopted?—16 candles.

5484. Not more than 16 candles?—No.

5485. (*Rear-Admiral Andoe.*) One lamp of 16 candles?—One lamp of 16 candles.

5486. (*Chairman.*) Is the mast-head light more powerful with the electric light, or how is that?—The mast-head light is also one lamp of 16 candle-power.

5487. Do you know, are the lamps generally with single filaments or two filaments?—The electric lamps?

5488. Yes?—Ours are single filaments. The ordinary Admiralty pattern 16 candle-power lamp has a single filament.

5489. That is a single one, is it not (*referring to a pattern produced*)?—That is a double filament; those used by Admiralty are single filament.

5490. I suppose oil lamps are always kept in reserve?—Yes, they are always kept in reserve where there is electric light installation. The lantern is fitted with both oil lamp and electric lamp.

5491. Of course, using vegetable oil, they are rather hard wicked?—Yes, they are.

5492. Now, as to screening these lights. We have been told the rule of the Admiralty is to regulate the screening by the distance ahead of the vessel at which the lights cross; is that within your province at all?—Yes.

5493. As we understand it, it is this, that in big vessels, they are made to cross at 200 yards ahead of the lamps; but for smaller vessels they are made to cross 150 yards ahead of the lamp?—Yes.

(*Mr. Bolam.*) Ahead of the stem?

5494. (*Chairman.*) Ahead of the stem?—Yes, those are the actual regulations.

5495. (*Chairman.*) "Fittings for bow lights are to be "so arranged that when the lamps are lighted they "should not be visible at all at more than three points "abaft the beam, to an observer at 200 yards distance "from the light. A screen, as shown on Plate 44, is "to be fitted so as to secure this.

"The screens ahead should be so fitted that an "observer approaching the ship from right ahead "would see the full rays from both lights up to a point "from 200 to 150 yards before the stem, between "which point and the ship the lights should appear "dim, gradually disappearing as the bow of the ship is "approached.

"The smaller distance of 150 yards is preferable for "ships with small beam, or ships with small transverse "distance between the lights, and the greater of "200 yards for ships with greater distance between the "lights.

"The lights should be tried in place to see if the "before-mentioned conditions are fulfilled, and if not "the necessary alteration to the fittings should be "made, A.S. 1357/89.

"The box for bow lights is to be constructed as "shown on Plate 44." I do not know what you consider a small transverse distance. At what sort of transverse distance do you make the change from 200 yards to 150?—No particular distance at all; that is a latitude which is allowed in all ships, but it is stated that the smaller distance is to be preferred for small vessels such as gunboats and vessels of that kind, and as you get to a battle-ship, for instance, that you should approach the greater distance, but there is no definite distance between those limits for any particular class of ships.

5496. I only want to know your practice, what sort of rule, if any, is laid down?—There is no rule; that latitude is given; it was considered by the Hydrographer of the Navy that it was no use laying down any more definite rule than that.

5497. If the distance was broad it was to be 200 yards, and if it was narrower it was to be 150 yards?—Well, it approaches those limits according to whether the ship is large or small, but anything between those limits is satisfactory; it is not so definite as the Board of Trade rule of 4°—the two rules may practically agree with a very broad ship; but, generally, according to the Admiralty rule, the lights would cross further from the bow than it would according to the Board of Trade rule.

5498. Have these rules been in force for a substantial time?—For a great number of years.

5499. And, as we have heard, the Admiralty did not make any change when the Board of Trade did?—Not upon the last Board of Trade Circular as to 4°. The Hydrographer thought it unnecessary to go into any more detail than is stated in those instructions.

5500. And, of course, the effect of that is that the Admiralty screening, speaking generally, is finer than the Board of Trade screening?—Yes.

5501. Have you any opinion yourself about that; do you think the fine screening is preferable or not?—I have no experience whatever as a navigator; it is entirely a navigator's question; but I agree with the Hydrographer, I do not see any utility in endeavouring to fix the lamps so that the rays must cross at a definite distance from the ship. A ship never runs on an exactly constant bearing, but is always in a constant state of slight yawing. Of course I am not a navigator, my own personal opinion is that it does not matter within reasonable limits.

5502. (*Rear-Admiral Andoe.*) You have had very great experience actually in the fittings of ships in dockyards, I think?—I have.

5503. Both as chief constructor and also in subordinate positions?—Yes.

5504. So that you have seen these screens fitted yourself under your own direction and observation?—Yes.

5505. And you have been present at the experiments which have taken place to test the position and the angles at which screens are placed, is that correct?—Quite correct.

5506. Of course you are quite aware that that angle materially differs according to the beam of the ship itself to which the light is screened?—Certainly.

5507. Therefore the broader the ship at a distance of two miles, we will say, for arguments sake, the greater distance a vessel will have to traverse to cross her bows in consequence of the coarser screening of the lights?—Yes.

5508. Have you ever had it brought officially to your notice that this material variation of the angle in different ships is considered objectionable by officers conducting these experiments?—I am not aware that we have had any complaints from commanding officers of the Royal Navy ships upon the subject.

5509. I mean officers connected with the dockyard—have they called special attention to the fact?—No, they have accepted the Admiralty instructions as satisfactory.

5510. Of course, the desirability of their crossing at larger or smaller angles is purely a seaman's question?—Quite.

5511. (*Captain Hughes-Hallett.*) Is there one standard pattern of Admiralty lamp throughout the service?—There is for ships; there is another pattern for very small vessels.

5512. The lamp, not the box?—The bow lanterns.

5513. The actual thing?—Yes, one standard pattern.

5514. And your boxes are, therefore, made upon a standard pattern?—They are made to receive the standard lantern.

5515. And they take any lamp that is drawn from store?—Yes, undoubtedly.

5516. After you have fixed the boxes, how do you regulate them to get an angle of crossing. If, upon experiments, the lights do not cross exactly at the 200 yards, how do you alter it?—The arrangements would

*Mr. H. E. Deadman.*
7 Aug. 1895.

be worked out upon paper as nearly as possible, and if there was any alteration required on trial it could be done in several ways, either by altering the fore-end of the screen or by putting a strip on.

5517. You do not put a chock, as they call it, like *this* (*referring to the plan*)?—Yes, we have done that. We have put on a small chock, but generally our screen is brought into the edge of the lens to begin with, further outboard than is shown there.

5518. (*Sir E. Harland.*) Then that necessitates a less chock here?—Yes.

5519. Meaning, perhaps, a very flat piece?—Yes. It is not often we have to alter to any great extent.

5520. (*Captain Hughes-Hallett.*) Then you set your screen, or the —— side of the box, whatever corresponds to that screen, to a calculated angle, do you, or with a line of the keel?—To a calculated angle.

5521. You set that from that angle at once?—Yes.

5522. You do not put the line of the keel and then a chock, or anything of that sort?—No.

5523. Then the actual thing is a structure that cannot alter; it is part and parcel of the structure of the ship itself, built into the ship?—Not always, it depends upon the class of ship, it may mean simply a box with a screen in front, secured in position on stantions; in larger ships we generally try to include it in the structure of the ship.

5524. So that there is no chance for any variation?—No, we look out for that. It can only be in the small class of vessels like torpedo boats that this liability would occur.

5525. Is there any minimum distance between the lights?—Athwartships you mean?

5526. Yes, between the lights in the athwartship line?—There is no Admiralty rule.

5527. As to the minimum distance?—No. On some of the torpedo-boat destroyers we have them fixed on the funnel as close together as 7 feet.

5528. They are actually together, back to back, in torpedo boats?—Yes, in small steam launches, but in ships it is generally considered that at the point where they are placed there is always sufficient distance between.

5529. But there is no regulation as to a minimum distance?—There is no regulation as to a minimum distance.

5530. (*Mr. Bolam.*) One of the staff commanders who gave evidence here put in a list of vessels, among them was the "Agamemnon," which carried a lamp beam of only 23 feet 7 inches. In that case, he said, the distance ahead at which the lights should cross would also be 200 yards. Does not that seem to violate the Admiralty rule?—They are very peculiar ships, with very narrow super-structures forward.

5531. He said, in that case, although the light beam was very small, still the light was made to cross at 200 yards. Is not that rather a violation of the Admiralty rule, where the ships have the lamps at a small transverse distance?—No, because the limits allowed in any ship are 200 yards to 150 yards; there is nothing definite between these limits.

5532 Because the angle at which that works out is only 1° 5′?—Yes. Of course, that would be very fine.

5533. You were present at experiments where the angles have been taken, and so on, in connexion with the screening of the lights?—Yes.

5534. Will you state what you do precisely?—We simply moor the ship in such a position that we can get measurements on shore, and the fore-and-aft line is produced, and after dark the lamps are lighted and actual observations are made by the reserve and dock-yard officers of the actual distance in front of the stem at which the full light is lost and at which it begins to fade.

5535. How do you determine the point at which it begins to fade; is it just a rough estimate?—It is a visual estimate unaided by photometric instruments.

5536. Have you any idea how much of the whole cross section of the light that would amount to seeing; would it be virtually the whole of the wick, or half of it, or what?—No. We make no measurements of that kind. It is difficult to fix a very definite point for crossing, that is why that latitude is given, anywhere between 150 yards and 200 yards. It would be very difficult to say that exactly at 200 yards your light was just beginning to fade. You would fix it within certain limits. You could tell between 150 or 200 yards.

5537. I should like to know definitely what these angles, which I have worked out from the Admiralty practice, amount to; whether it means these angles are from the inside of the wick, or the middle of the wick, or the outside of the wick? One witness thought it practically meant from the centre of the wick?—I could not tell you that. We do not use the angles, and therefore that has not come under my observation. We simply observe the point at which the light loses its full power and begins to dim.

5538. You stand at a spot, do you, observing the lights?—We gradually approach the ship. We get away beyond 200 yards, and we walk up until we get to 200 yards, and at that distance we expect to see both lights full. If the light begins to fade before we get to the 200 yards then the screen wants altering.

5539. I should rather have thought you would have stood at the 200 yards and signalled to the man looking after the screens, and allowed him to work the screens in and out till the lights showed, or put chocks on of different sizes?—Yes, that would be done if we found that we wanted chocks. For instance, if we got within 150 yards and found the lamp was still showing, and we could see either light, then we should put on a small piece of chock and try again till we got the chock of the correct thickness.

5540. (*Sir E. Harland.*) You referred to the side lights being placed very much with regard to the position of the mast?—Yes.

5541. But in giving that answer, does it occur to you that the position of masts in ships now-a-days is a very unknown position, that is to say, they vary so much, so many ships having only one mast, and that being abaft amidships in some cases?—Oh yes, that would be a special case, but in that case we should put up a mast for the light alone, which I should call a foremast in that case.

5542. What sort of a mast?—An ordinary pole mast.

5543. What sort of mast, do you mean that for the masthead light?—Yes, of course, I was referring at first to an ordinary rigged ship. Where you come to a ship with only one military mast that will not apply; a pole would in this case be required to carry the mast-head light, and then we should try and fit the side-lights abreast that pole if possible.

5544. Then are some such poles fitted to some of our large line of battle ships?—Yes, they are fitted to the battle ships of the "Admiral" class.

5545. Then how is it fixed; has it rigging to it and shrouds?—Yes; it is stayed as necessary to support it.

5546. Then are the side lights in that case placed opposite that masthead pole?—Yes, as nearly as possible; we cannot always do it, other conditions come in.

5547. Are they placed there with the object of getting them away from the position of some of the guns at the side, upon the principle that the guns could not be placed at the side exactly where the rigging of that pole mast is secured?—No, the principal object is to get them in the same athwartship plane as the side lights.

5548. Then are you aware of the commanders of these vessels preferring to have their side lights immediately below the masthead light so far as possible?—I have always understood that that is desirable.

5549. Then you have not heard them express any opinion that it would be better to have the side lights abaft the masthead light?—No, I have not.

5550. To enable them to judge at a distance in what direction a ship was sailing, for instance?—No, I have not heard that.

5551. Then, in that case, the side lights in your opinion are placed more with the object of having them below the masthead light?—Just so.

5552. And then the masthead light is placed with what object; why is the masthead light placed at any

particular spot; is it placed in view of any deck-fittings or guns?—That would be the case.

5553. So that it would in no way interfere with the freedom of action of the guns?—Just so.

5554. So that in that view the lights became subservient, as far as position is concerned, to the position of the guns in the vessel?—They must in a man-of-war to a certain extent, but in a design all these points are considered together and each given its due consideration and weight.

5555. Then are these lights accessible from the bulwarks of the vessel at all, for trimming and placing in position?—Yes.

5556. In that case, then, they are placed very similarly, for practical purposes, to some of the merchant ships, and they are secured in what are called lighthouses?—Yes, in cases where we have a closed-in forecastle they are very often fitted so as to be get-at-able inside; where they are placed on the top of the forecastle in some ships we have arranged for them to be put up from the bottom.

5557. So that, practically speaking, they are more or less in something like what are called light boxes?—Quite so, except there is no separate lens in the box, the lens of the lamp is the only lens; there is simply a hole cut out in the box for the lens.

5558. That is so, that the only glass exposed to either the light, or the sea, is the simple lens of the lantern itself?—Yes.

5559. Then, with reference to these lights, you say they are generally 16-candle power. Does that apply to the red and green lights?—It applies to both.

5560. You are not aware of any more intense light being given to the green light?—I am not.

5561. You also observed that there was a degree of latitude given to somebody as to whether the rays should cross at 150 yards or 200 yards ahead. To whose discretion is that left? Is it left to the discretion of the commander of the vessel for the time being, or the captain, or the admiral?—When the test is made by the reserve and dockyard officers before the ship is placed in the fleet reserve, if those conditions are fulfilled, that is, if the light begins to grow dim anywhere between the 200 and the 150 yards, that would be considered satisfactory.

5562. Then, in that case, you would at once admit that the distance between the lights being probably very varied, in those various ships, that that would leave a very considerable difference in the angle?—Yes, undoubtedly.

5563. Then, following that up, you referred to some side lights being carried on each side of the funnel in some of the torpedo catchers?—Yes.

5564. And even in one instance where they were carried back to back. At what distance would this angle be arranged for the lights to cross—would it be the same, 150 yards ahead?—I am not aware that there is any rule with regard to that, only the simple placing them back to back is accepted.

5565. But would you not be able to determine beforehand at what distance the lights even in that case should be made to cross, or in other words, would not that at once necessitate the screens being very much finer, as we have called it?—Yes. I do not think that the same importance is attached to the fitting of very small boats, as it would be in larger ships; certainly, there are no definite regulations to my knowledge; no special trials are made.

5566. Not by night in dock?—Not by night.

5567. Then, so far as you are aware, they possibly would arrange that they should cross at 150 yards ahead the same as other small vessels?—Yes, it is possible; there is no definite rule laid down with regard to that. I do not think it is considered to be a matter of importance whether they cross at once or 100 yards ahead in those small vessels where lamps are obliged to be placed so close together.

5568. Are you aware, where oil is used, if it is American or Colza oil that is used?—Colza oil is used.

5569. Would that be in view of American oil not being permitted in general use on board ships in case of fire?—That is the reason.

Mr. Thomas David Taylor called and examined.

5570. (*Chairman.*) I think you are a surveyor under the Board of Trade at Greenock?—Yes.

5571. I think you have been good enough to make out a table* showing the various percentages of vessels which had their lights screened one way or the other in 1893?—Yes.

5572. That would represent their screening before the new rule was in force?—Yes.

5573. First of all, how many vessels did you take the screening of?—Over 100.

5574. And upon what principle, if any, were they selected?—They were not selected at all. I just took them as they came into the port, indiscriminately.

5575. You just took the first 100 that came into the port?—The first 100 that came into the port after the order came out about the end of November, 1892.

5576. So that the first 100 that came into the port you took particulars of, in order to show actually what screening at that time they adopted?—No, it was not for that purpose I took it. I took it in order to see how the screens were arranged for the purpose of putting them to the 4° angle.

5577. So that you found out what their screening was?—I found out what they were before I could adjust them.

5578. This table (*produced*) as I understand, shows the results?—Yes, it practically shows the results.

5579. But you took notes, I think, from which this table was made up, did you not?—Yes, it is all *here* in *this* list which is handed in to you. I think it gives the vessels.

5580. Did you ascertain, before making out that list, that the screening had not previously been dealt with by any other surveyor?—Yes, I made a point of that in every case.

5581. And so you were pretty sure that the screenings represented upon that were the screenings actually in force before the new rule came into operation?—That is so.

5582. I think, further, you did ask, did you not, of the master or officer in charge whether, in his judgment, the side lights in fact crossed?—Yes.

5583. What were the answers you got?—With the exception of about four or five young officers, they were all under the impression that the lights showed in a line straight ahead of the ship, that is, parallel with the centre line of the vessel. But about five or six of the young officers that had just been through the schools were aware of the fact that the lights converged, but they were not aware how much.

5584. Those are the actual vessels, are they?—Those are the actual vessels.

5585. I see there are a certain number of sailing vessels?—And some steam; all the sizes are given.

5586. Now, may I take the first steamer as an illustration, the "Clymene." She is 1,463 tons gross and 942 tons net. You surveyed her on the 18th January, and there you found the convergence of the side lights was 3°. Now, is that measuring from the outside of the wick?—Yes.

5587. Then, I do not quite understand this, I am afraid. You have got 3° and 3° as the convergence of the side lights, and then you have another figure of convergence when the screens are parallel?—Yes, that is a case where the screens are not actually parallel to the longitudinal centre line of the vessel. You see the screens were supposed to be parallel. They may have got out of their places, so, of course, that gives the actual convergence of the lights, and this gives the convergence supposing the screens were placed parallel as they were supposed to have been.

* *See* Appendix, No. 16.

*Mr. T. D. Taylor.*

7 Aug. 1895.

5588. I see this gives, as indeed your table shows, a very great divergence indeed; in fact, a great many varieties; for instance, I see the highest goes up to 9°. Only one of the vessels goes up to that. Which was that? I wonder if you could find me that vessel?—There is one here, the "Enterprise," of Dublin. She is only a small schooner.

5589. She is only 39 tons net, but she is a sailer, and the actual convergence of the side lights is from 8° to 9°, and when the screens were placed parallel, 9° and 10°?—Yes.

5590. The only thing I should rather like to ascertain is this; this statement does not show, of course it can easily be worked out from that—?—I have given the percentage at the end if you look.

5591. But what I wanted to ascertain was, whether or no the larger vessels were generally the finer screened ones, or whether it is the smaller vessels. I asked you for the very largest in order to ascertain whether it was the smaller vessels. That turns out to be a very small vessel. Is it generally the case that the higher degrees of screening are to be found in quite the smaller vessels, and the lower degrees of screening are to be found in the large vessels?—No, I think you will find it is very much mixed between the large and the small, if you look over the list and compare it with the tonnage.

5592. I was tempted to ask the question because just the first few vessels would seem to point in that sort of direction. For instance, here is the "Bostonian" which is the first very large vessel. She is a vessel of 4,668 tons gross and 3,030 tons net. She is screened actually to 1¼° and 1½°, and when the screens are parallel it is 1¼ and 1½, so that her screens are in the right position?—Yes.

5593. So there she was screened very fine. Now, here is the "St. Enoch," she is almost as big. She is 4,298 tons gross, and 2,746 tons net. She is screened 5° and 4¾°. Again, her screens being in the right position. Here is a vessel of 3,318 tons gross and 2,136 tons net, the "Parkmore." She is screened to 3½° and 3½°. Now, when I get down to the little ones—here is one of 165 tons, the "Herbert." She is screened 7½° and 6°, so that it looks a little, of course I am only taking it very roughly, as if the big vessels were screened rather more finely, and it is the small vessels that bring up these very great figures?—Yes, the larger vessels were really screened very finely in a few instances. There is no doubt about that.

5594. Of course there are some large ones here. Here is one of 5,000 tons, where the screening is exactly 4°; and here is one of 4,500 tons, where the screening is 5½°?—No, 4½° in one and 5¼° in another.

5595. So the screen was evidently out of place?—The screen was evidently out of place.

5596. (*Rear-Admiral Andoe.*) I understood the Chairman to say those reports were of mixed steamers and sailing vessels?—Yes.

5597. Did you find the sailing ships were coarser screened, as a rule, than the steamers, speaking generally?—Yes, I think I did.

5598. And in most cases, I think I understood you to say, where you found fine screening it was in the case of large steamers?—Yes, that is so.

5599. (*Chairman.*) I think a glance will show that; wherever you see a large steamer you will generally find fine screening, and with the small vessels you will generally find coarser screening?—Yes. The steamers in one or two of the large companies have their lights screened very finely.

5600. (*Rear-Admiral Andoe.*) Do they seem to prefer it?—Of course I cannot tell, I suppose the superintendent had looked particularly to them in those cases.

5601. (*Captain Hallett.*) Do you have anything to do with the placing of the masthead light—the supervision of placing the masthead light at all—the white light?—Oh yes, I have got to see to all the lights.

5602. To see that it is not too low down?—Yes.

5603. Do you have any limit with regard to the height above the side lights?—Yes.

5604. Do you allow them to place it as high as they like?—Oh no, we seldom allow it to be any higher than a height equal to the beam of the ship, that is providing it is not under 20 feet.

5605. That is the height up?—Yes.

5606. But if they chose to put it 40 feet?—Well, if the beam of the ship was 40 feet, of course we would allow them to place it at that height.

5607. Then it is always placed at a height corresponding with the beam of the ship, is that what I understand?—Well, it is never supposed to be under that, but of course if the beam of the ship is very small—supposing it is only 15 or 18 feet—then the limit is to be 20 feet.

5608. Then where do you measure that from, above the side lights?—From the deck of the ship.

5609. If you measure that from the deck of the ship, and that vessel is carrying her side lights upon a very high bridge, you would have them exceedingly close?—Well you get them much closer, of course; there would be no doubt about that.

5610. The distance of the masthead light above them is limited, I think, according to the law, is it not?—Yes, and by the height of the fore lower mast.

5611. I wanted to ascertain whether anything was done in that way, because a complaint has reached my ears of the extreme height at which some of those fellows carry their side lights?—The general understanding amongst the surveyors is to fix the white light the height up that the ship is broad.

5612. Above the coloured lights, do you mean?—Yes, if the beam is 40 feet, to set the white light that height up.

5613. Above the coloured lights?—Well it is generally taken from the deck.

5614. (*Mr. Bolam.*) The words in the rule are "above the hull," is that how you interpret it?—Yes, "above the hull," it is taken from the deck of the ship.

5615. (*Captain Hallett.*) You have no instructions?—I do not think there are any specific instructions.

5616. (*Mr. Bolam.*) How long have you noticed the screens of the Clyde vessels to be; by screens I do not mean the whole length of the screen, but just the distance from the front of the lens to the chock?—Well, they vary from about 36 to 64 inches.

5617. (*Chairman.*) They are all given here. When you say the length of the screen, you mean from where to where?—From the wick *in* the lamp to the cutting point at the end of the screen.

5618. (*Mr. Bolam.*) Is that the chock?—Yes, the after edge of the chock.

5619. That is, wick to chock—there is no doubt about that?—No, there is no doubt.

5620. What is the largest angle you ever screened lights to, yourself, in your own practice?—Well, as a matter of fact, I have never really tried the angles, because we used to screen them before the present rule came into force, so as to keep the screen parallel to the centre line of the ship, and then the inner edge of the lens and the outer edge of the chock are parallel to the screen.

5621. So that yourself and your brother surveyors may really be responsible for these large angles?—Well, I do not see that exactly, because the lamps are made by makers all over the country, and they vary very considerably. There is no doubt about that. In fact, I have got one ship where the wick was an inch further out in one lamp than in another; consequently it makes a difference of nearly 2° in the angle.

5622. At any rate, in the large companies, where the screening is attended to, and the safety of navigation is specially attended to by the superintendent, your experience in the Clyde is that the angle was distinctly small?—Yes, in one or two cases; the table will show that.

5623. (*Sir E. Harland.*) As the apparent result of looking over your list of screening shows that the larger ships were screened to a finer angle, do you think that that has arisen from the larger ships having longer screens?—Oh, no, not at all; some of the larger ships have only got 36-inch screens, and some of the medium sized ships—a medium sized ship I have there, for instance, is 64 inches—she is 1,800 tons.

5624. Then, prior to 1892, was there no general instruction and no uniformity of screening amongst the Board of Trade surveyors as to either the angles or the length of the screens?—Yes, there was an instruction to this effect, that, where the lights are placed amidships or far aft, the surveyor was to take

care that the lights did not converge too near the stem of the vessel.

5625. But there was no instruction or recommendation as to the length of screening?—No, nothing particularly specified, but it states that in such cases the screen ought to be increased in length so as to reduce the angle.

5626. And was that before the idea occurred to them that putting a chock on them would ensure the same purpose?—Oh, no, the question of chock was gone into.

5627. But would it not have the same effect?—Of course it would, but you see there was no specific angle fixed, and consequently the surveyors had very much to follow out their own judgment.

5628. Then, do you really mean this, that the surveyors were bound to see that there was a pair of side lights in the ship, but as to the length of screen, or as to the angle they should be screened at, that was a matter very much left to the caprice or choice of the captain or marine superintendent of the company?—Well, that I cannot say; it is not supposed to be left to the captain or to the marine superintendent or anybody else; it is supposed to be a question for the surveyor to fix, and he is supposed to have a specific rule to fix it by.

5629. Was there a specific rule before 1892?—Yes.

5630. Then how is it, if that is so, that the surveyors at various ports seemed to have neglected that specific rule?—I do not know about neglecting it, but the varieties in the angles of convergence in ships' side lights depend very much upon the lamps and the rule itself.

5631. (*Chairman.*) In these vessels, exhibiting these great varieties, did you find the chock was in the line with the inner edge of the lens?—Yes, as a rule.

5632. So that these varieties are attributable really to the difference, mainly, in the lights used?—Yes, in the lamps used and in the position of the wicks in the lamps.

5633. (*Sir E. Harland.*) Then there was no attempt on the part of the various local surveyors to induce the lamp manufacturers to go by one uniform distance from the inner edge of the lamp to the centre of the wick?—No, I am not aware that there was; of course, according to the rules, the wick was supposed to be placed in the centre of the lens, but, as a matter of fact, you do not get them that way, as a rule they may be a half or three-quarters of an inch, either further in or further out, than they ought to be. Of course we cannot condemn the lamps for a thing of that sort.

5634. But you are not aware of there being any fixed position for the distance of the inner edge of the wick from the face of the lantern?—No, it really varies from about 4½ to 6 inches from inner side.

5635. Lamps, perhaps, in the same ship?—No, not in the same ship, in different ships.

5636. So that the screening which you superintended for a certain angle in the ship, with a certain set of lights, it was possible there that the owners might purchase another set of lights soon afterwards, and ship those lights with a difference of an inch, or an inch and a half, as to the position of the wick?—That is so.

5637. And so alter the angle tremendously?—Yes, I know one case—I surveyed the vessel—and I found they had lost one of their original set of side lights, and they had picked up an odd one somewhere, and the wick in the odd one was about an inch further out than in the original one.

5638. In view of that as your experience, and in view of its being desirable to have some uniform angle determined, whatever it may be, would you advocate that there should be some standard distance determined upon as to the distance of the wick from, say the inner face of the lantern, so as to enable any duplicate lanterns in the ship, when shipped in that receptacle, to be certain to show all the light at a proper angle?—Oh, yes, it would be very desirable, no doubt.

5639. Are you aware of any practical difficulty in that?—No. I am not aware of any practical difficulty.

5640. Do you suppose that a lamp-maker would object, or cause any trouble, upon the score of extra expense, if he were required to make his lamps, in future, with the wick a certain distance from the inner face of the lantern?—No. I do not see that there could be any possible objection to it myself. In fact, it would be a very desirable thing, and it would save a deal of trouble in many ways.

5641. Here, for instance, is a starboard lamp. Assuming that one or two, perhaps three, different sized lanterns, standard size, that is the largest ones for the largest ships, and the smallest size, number three, say, for the smallest ships; do you see any objection to the distance from the centre or edge of the wick being, in such cases, a fixed distance from the inner face of the lantern, so that when it is shipped into its box, or whatever the name of the receptacle may be, that it will ensure that whatever one of these particular sized lamps might be, the angle of screening would always be certain to be the same?—I see no objection whatever. It would simply mean that the distance between the inner edge of the lens here and the lamp would require to be varied in large and small lamps; but with that exception I do not see that there need be any difference.

5642. But why do you mention the edge of the lens, because it in no wise gives out any light?—No, but you would not get the convergence in larger lamps; supposing you had the side of the lamp away here, and you brought the wick in to a uniform distance, you might not have the convergence necessary. That is the only point.

5643. But assuming it, for simplicity's sake, in no case should the inner edge of the lens be beyond the outside of the inner edge of the wick?—No, I do not see it.

5644. Are you aware in comparing lamps that the lens really has nothing to do with the direction of the light leaving the wick and striking the chock?—It is not supposed to be, but I have found lamps made where part of the lamp really covered the wick altogether, when looking straight ahead of it, in certain makes of lamps.

5645. We have not found a single case of that sort.

5646. (*Rear-Admiral Andoe.*) In the commoner lamp, I suppose?—Not in that make; in one with a small cylindrical lamp that goes inside.

5647. (*Sir E. Harland.*) With reference to the height of the masthead light, the instruction being you say not more, and certainly not higher than the beam of the ship, and that the surveyors would object if it was unusually high, upon what principle would you object?—Well, there is no particular instruction upon that. It has been an understood rule that such was the case.

5648. You also state that the height of the masthead light should not be less than the breadth of the beam of the ship above the deck?—No, I said that they should never be less than 20 feet; and where the beam of the ship was, say, 40 feet, they ought not to be lower than 40 feet.

5649. And you are not aware of the principle upon which that rule was determined?—Well, I suppose the principle that it was based upon was the principle that the white light and the red and green lights ought to form a certain angle—ought really to form an equilateral triangle—that is the object of it.

5650. That is when you are stem on?—Well, stem on principally.

5651. Then, have you any instruction, or do you give any advice in any way as to whether the side lights should be abaft the masthead light or before it?—No, we take no action at all about it.

5652. (*Chairman.*) There is one thing I wanted to ask you. I see the length of the screens vary very much indeed; what was your practice before the new rules as to the length of screen, how far did you control its length?—Well, I allowed them to have the length of screen 36 inches from the outside of the lamp, that would make it about 42 inches from centre of wick.

5653. Because some screens I see here go up to as much as 64 inches. How do you account for that? Do you think that was because they escaped the observation of the Board of Trade surveyors, or that the Board of Trade surveyors at some ports did not care really about the length of the screen?—Well, I really cannot say what to attribute it to exactly, because no doubt there is a very great difference in the length of the screens; but, of course, according to the rule, which was in existence before the present rule came into force, the surveyors were allowed to increase the length of the

*Mr. T. D. Taylor.*

7 Aug. 1895.

screen according to the distance the screen was abaft the stem of the vessel, so as not to allow the lights to converge too close to the stem, and it is possible upon that account that the difference comes in.

5654. Because it seems a little odd to find this great variety in the length of the screens if there was any uniform rule practically in force with regard to these screens. I suppose the truth is that it was not able to be strictly observed?—No, there was not particularly strict uniformity in it.

5655. (*Sir E. Harland.*) Did you check the screening of any of the lights carried in what I call lighthouses?—Oh, yes.

5656. And did you find them pretty accurate, or did they vary much from the usual screening in other ships, in view of their being a comparatively new structure?—No. I found them very accurate as a rule.

5657. And did you find any difficulty in checking them or taking your measurements?—Well, of course it is more complicated to fix angles where you have got light towers, but still it can be done very readily by anyone who has any experience in laying off and sighting; of course where the whole thing comes in, in my opinion, is that the chocks have been fixed to the screens upon the supposition that the screens were parallel to the centre line of the vessel, when they really were not, because it is very difficult in some instances to know whether they are or not, and the only way in which you can check the angle accurately is to project the inner ray of light about 50 or 100 feet forward, or on to a forecastle. Then by setting up sighting battens at that point where the inner rays should cross; the outer edge of the wick and the chock should be in a straight line with the battens, if not, the chock should be made larger or smaller as may be found necessary.

5658. But you have found much greater difficulty in checking those angles in lights carried in lighthouses than with open screening?—Yes, of course it is more complicated, but it can be done with the greatest accuracy by anyone who goes into those matters carefully.

## LIGHTS FOR STEAMERS.

When under Weigh.

A Bright White Light on the Foremast Head.
A Green Light on the Starboard Bow.
A Red Light on the Port Bow, to be fitted with inboard *Screens*.

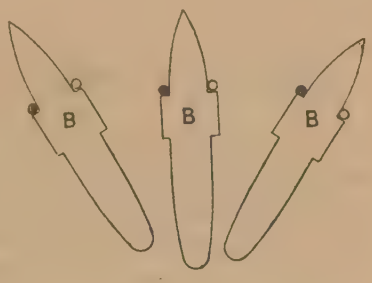
When at Anchor.

A Common Bright Light (Steamers and all other Vessels).

*The following Diagrams are intended to illustrate the working of the above Plan.*

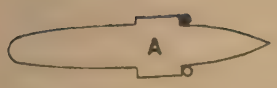
### 1st Situation.

In this situation the Steamer A will only see the *red light* of the Vessel B, in whichsoever of the three positions the latter may happen to be, because the *green* light will be hid from view. A will be assured that the *larboard* side of B is towards him, and that the latter is therefore crossing the bows of A in *some direction to port*. A will therefore (if so close as to fear collision) *port* his helm with confidence, and pass clear. On the other hand, the Vessel B, in either of the three positions, will see the *red*, *green*, and *mast-head* lights of A appear in a triangular form, by which the former will know that a Steamer is approaching *directly* towards him:—B will act accordingly.



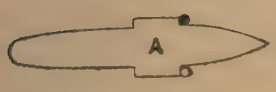
It is scarcely necessary to remark that the *mast-head light* will always be visible in every situation till abaft the beam.

### 2nd Situation.



Here A will see B's *green* light only, which will clearly indicate to the former that B is crossing to starboard. Again A's *three* lights being visible to B, will apprize the latter that a Steamer is steering *directly* towards him.

### 3rd Situation.



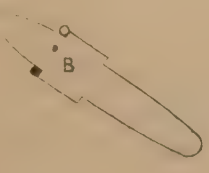
A and B will see each other's *red* light only. The screens preventing the *green* lights being seen. Both vessels are evidently passing to *port*.

### 4th Situation.

Here a *green* light only will be visible to each: the screens preventing the *red* lights being seen. They are therefore passing to *starboard*.

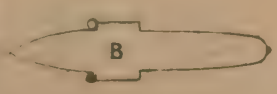
### 5th Situation.

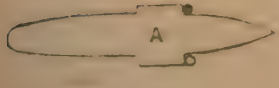
This is a situation requiring caution:—the *red* light in view to A, and *green* to B, will inform both that they are approaching each other in an oblique direction. A should put his helm to port, according to the standing rule mentioned in the next situation.



### 6th Situation.

Here the two coloured lights, visible to each, will indicate their *direct* approach towards each other. In this situation it ought to be a *Standing Rule* that both should put their helms to *port*. This rule is already pretty generally adopted; but it would add to safety if it were made *imperative*: for it is evident, that without some rule of this kind, well understood and practised, it will be impossible to guard at all times against accidents in the situation of the two Vessels here given.





App. 1, Nos. 1 and 2.

B.—Extract from the Admiralty Rules of 1848, published in the London Gazette of July 11, 1848.

1. The masthead light to be visible at a distance of at least five miles in a clear dark night, and the lantern to be so constructed as to show a uniform and unbroken light over an arc of the horizon of twenty points of the compass, viz. from right ahead to two points abaft the beam on each side of the ship.

2. The coloured side lights to be visible at a distance of at least two miles in a clear dark night, and the lanterns to be so constructed as to show a uniform and unbroken light over an arc of the horizon of ten points of the compass, viz., from right ahead to two points abaft the beam on their respective sides.

3. The side lights to be moreover fitted with inboard screens, of at least three feet long, to prevent them from being seen across the bow. The screens to be placed in a fore-and-aft line with the inner edge of the side lights.

C.—Extract from the Admiralty Rules of 1852, published in the London Gazette of May 7, 1852.*

1. The masthead light is to be visible at a distance of at least five miles in a dark night, with a clear atmosphere, and the lantern is to be so constructed as to show a uniform and unbroken light over an arc of the horizon of twenty points of the compass, being ten points on each side of the ship, viz., from right ahead to two points abaft the beam on either side.

2. The green light on the starboard side is to be visible at a distance of at least two miles in a dark night with a clear atmosphere, and the lantern is to be so constructed as to show a uniform and unbroken light over an arc of the horizon of ten points of the compass, viz., from right ahead to two points abaft the beam on the starboard side.

3. The red light on the port side is likewise to be fitted so as to throw its light the same distance on that side.

4. The side lights are moreover to be fitted with screens, on the inboard side, of at least three feet long, to prevent the lights from being seen across the bow.

D.—Extract from the Admiralty Rules of 1858, published in the London Gazette of March 5, 1858.

2. The masthead light shall be so constructed as to be visible on a dark night, with a clear atmosphere, at a distance of at least five miles, and shall show an uniform and unbroken light over an arc of the horizon of twenty points of the compass, and it shall be so fixed as to throw the light ten points on each side of the ship, viz., from right ahead to two points abaft the beam on either side.

3. The green light on the starboard side and the red light on the port side shall be so constructed as to be visible on a dark night, with a clear atmosphere, at a distance of at least two miles, and show an uniform and unbroken light over an arc of the horizon of ten points of the compass, and they shall be so fixed as to throw the light from right ahead to two points abaft the beam on the starboard and on the port sides respectively.

4. The side lights are to be fitted with inboard screens projecting at least three feet forward from the light, so as to prevent the lights from being seen across the bow.

No. 2.—Instructions issued by the Board of Trade to Surveyors, 1868–1891.

A.—*Instructions issued in* 1868.

The attention of the Board of Trade has frequently been called to the want of uniformity in the range of the lights of seagoing ships, and in the position of the screens and other fittings. The Board of Trade have, therefore, after consulting the Board of Admiralty and the Elder Brethren of the Trinity House, decided on issuing the following instructions:—

1. The surveyors of steam vessels, appointed under section 305 of the Merchant Shipping Act, 1845, and the inspectors of lights and fog signals, appointed under section 30 of the Merchant Shipping Act Amendment Act, 1862, should be very particular in examining the lanterns containing the masthead light, and the coloured side lights of steam and sailing vessels. They should satisfy themselves—

*First.*—That these lights are, as required by Article 3 of the Regulations, of such a character as to be visible on a dark night with a clear atmosphere to the distance therein named, viz., the fore-mast-head light of steam ships a distance of at least five miles, and the coloured side lights of both steam ships and sailing ships a distance of at least two miles. These conditions are to be complied with without reference to the size of the ships carrying these lights.

*Secondly.*—That the lantern containing the masthead light for steam ships under weigh is so constructed and is so placed as to show the light from right ahead to two points abaft the beam on each side.

*Thirdly.*—That lanterns containing the coloured side lights of steam and sailing ships are so constructed as to show the coloured light from right ahead to two points abaft the beam, on the starboard and port sides respectively. It has been represented to the Board of Trade that lanterns are being constructed and sold that cannot show the lights in the required directions, on account of insufficient range of lens or other defects of construction. The surveyors must not on any account pass lanterns for either masthead or coloured side lights unless satisfied that they are so constructed as to throw the light in the required directions.

Glasses for these lanterns are usually cast in circles. Inferior lanterns contain only a quarter of a circle, and when this is the case they cannot be depended on.

The surveyor should be careful to look closely into this. (*See* Figs. 1 and 2.)*

*Fourthly.*—That the lanterns, burners, lenses, and reflectors are in good and serviceable condition.

*Fifthly.*—That lanterns containing the red and green side lights are so placed that the lights will not be obscured by any of the fittings of the vessel.

In inspecting or surveying the lanterns, special care should be taken that they are clear of catheads, boats, boats' davits, sails, and rigging, &c.; with this view care should be taken that the side lights are not placed too far aft. The best position for the lantern containing the side lights of steamers is generally abreast of the foremost shroud of the fore rigging. The surveyor will not, however, insist upon their being placed in this position, but will suggest it to the owners, and make a note on the papers when he thinks that the lights are badly placed, and when the owners refuse to alter their position.

The position of the lamps must be, of course, to some extent governed by the size, form, and rig of the vessel; but in the absence of special circumstances, the side lights should not be passed by the surveyor or inspector if they are placed abaft the broadest part of the ship; and if in any case he passes them when they are placed abaft the broadest part of the ship, he should forward a special report to the Board of Trade stating the special circumstances of the case.

*Sixthly.*—That there are suitable and proper fittings for the lamps and screens. The practice of attaching the lamps to screens secured to the rigging alone must be discouraged.

*Seventhly.*—The Regulations require that the coloured side lights shall be fitted with inboard screens projecting at least three feet forwards from the lights. Care must be taken that the screens are three feet long, or such greater length as the position of the light with regard to the screen and its distance from the head of the vessel may render necessary.

* The following note is attached to the Regulations of 1852:—"The "system of night lights laid down in the above Regulations has been "adopted in Her Majesty's Service and by the Governments of the "principal Foreign Maritime Nations."

Inferior lamps contain a lens of only a quarter of a circle.

*Lamps fitted with lenses of only a quarter of a circle are generally defective in range, should always be looked on with suspicion and should not be passed unless the light is seen clearly to show over the required arc of 10 points of the compass.*

*Lenses should be of the range shown above, viz. an arc of 10 points of the compass.*

*To facce page 198.*

Fig. 7.

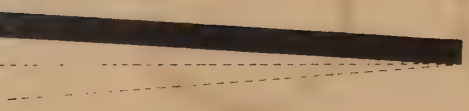

Fig. 8.

Wyman & Sons, Lᵗᵈ, Lith. 7160-6-95.

The surveyor would do well to observe the effect of alterations in the distance of a side light from its inboard screen. He should also bear in mind that if the lantern is placed at a few inches outside an ordinary straight screen of three feet in length, or even against such a screen, the rays of light will be found to cross the end of the screen so as to be visible to a vessel approaching upon the opposite bow. (*See* Fig. 3.)*

If the surveyor finds that the red and green rays cross each other, he should of course have the defect remedied at once. There are many ways of doing this; for example, the screen may be lengthened; or another board may be placed outside it (Fig. 4); or a chock (equal in thickness to the distance between the inner edge of the lens and the side of the screen) may be secured to the fore end of the screen (Fig. 5); or the lamp may be so placed that the outside of the screen will come against the inner edge of the lens (Fig. 6); or the screens may be so placed that the distance across the ship between their outer sides at the fore end shall be equal to the distance between the inner edges of the lenses of the two lamps. (Fig. 7.)

If the red and green rays cross each other immediately on passing the stem, the red light will be seen on the starboard bow, and the green light on the port bow, as shown in Fig. 8; but on the other hand, if they do not cross, at least to a slight extent, then they cannot both be seen ahead.

The real points to be studied in fixing and arranging the inboard screen appear to be—

*First.*—To ensure that the rays of the red and green side lights do not cross each other immediately on leaving the ship, nor at all more than is possible; and,

*Secondly.*—To ensure that the distance ahead within which neither light is seen is not greater than can be avoided.

2. When the surveyor is inspecting the lamps of a tug steamer under the Merchant Shipping Act of 1862, or is surveying for a passenger certificate under the Merchant Shipping Act of 1854, a steamer which he has reason to believe is or will be employed in towing other vessels, he will require the steamer to be provided with two properly constructed masthead lamps, in strict accordance with Article 4 of the Regulations.

3. The surveyor will also see that every steam or sailing vessel which he surveys or inspects is provided, in accordance with Article 7 of the Regulations, with a globular lantern, of at least eight inches in diameter, to be used when riding at anchor.

4. Whenever the surveyor is called on to survey crew spaces under the Act of 1867, he should also inspect the lights and fog signals under the Act of 1854.

5. He should point out to owners and masters the necessity of a strict compliance with the Regulations; and, in carrying into effect the instructions contained in this circular, he should do all in his power to prevent unnecessary delay or inconvenience; but if an owner or master objects or refuses to make the alterations or additions which the surveyor points out as necessary, a report on the Form Stm. 21 is to be sent at once to the collector of customs, who will thereupon, under section 30 of the Merchant Shipping Act Amendment Act, 1862, refuse to grant the vessel a clearance until he receives from the surveyor a report, on the Form Stm. 22, that the Regulations are complied with. A similar report to that sent to the collector is to be sent to the master or owner.

THOMAS GRAY,
Assistant Secretary, Marine Department.

*Note.*—Supplies of this circular should be obtained by the surveyors in the usual manner from the superintendents of mercantile marine offices, and copies should be given to any masters or owners of ships desirous of having them.

* Plate I.

B.—EXTRACT from the INSTRUCTIONS to SURVEYORS issued in 1872.

If the surveyor finds that the red and green rays cross each other, he should of course have the defect remedied at once. There are many ways of doing this: for example, the screen may be lengthened, or another board may be placed outside it (fig. 4); or a chock (equal in thickness to the distance between the inner edge of the lens and the side of the screen) may be secured to the fore end of the screen (fig. 5); or the lamp may be so placed that the outside of the screen will come against the inner edge of the lens (fig. 6); or the screens may be so placed that the distance across the ship between their outer sides at the fore end shall be equal to the distance between the inner edges of the lenses of the two lamps (fig. 7).

C.—EXTRACT from the INSTRUCTIONS of 1875.

The inboard screens should be so fitted as to prevent the red and green rays crossing too close to the ship. There are many ways of doing this: for example, the screen may be lengthened, or another board may be placed outside it (fig. 7); or a chock (equal in thickness to the distance between the inner edge of the lens and the side of the screen) may be secured to the fore end of the screen (fig. 8); or the lamp may be so placed that the outside of the screen will come against the inner edge of the lens (fig. 9); or the screens may be so placed that the distance across the ship between their outer sides at the fore end shall be equal to the distance between the inner edges of the lenses of the two lamps (fig. 10).

For both lights to be seen ahead it is necessary that the red and green rays should cross at a certain distance ahead. Surveyors will probably find that if the inboard edge of the wick touch a line that is parallel with the keel of the ship, and that cuts the outer edge of the forward end of the inboard screen, the rays will cross suitably.

D.—EXTRACT from the INSTRUCTIONS of 1879.*

The inboard screens should be so fitted as to prevent the red and green rays crossing too close to the ship. There are many ways of doing this: for example, the screen may be lengthened, or another board may be placed outside it (fig. 7); or a chock (equal in thickness to the distance between the inner edge of the lens and the side of the screen) may be secured to the fore end of the screen (fig. 8); or the lamp may be so placed that the outside of the screen will come against the inner edge of the lens (fig. 9); or the screens may be so placed that the distance across the ship between their outer sides at the fore end shall be equal to the distance between the inner edges of the lenses of the two lamps (fig. 10).

For both lights to be seen ahead it is necessary that the red and green rays should cross at a certain distance ahead. Surveyors will probably find that if the inboard edge of the wick touch a line that is parallel with the keel of the ship, and that cuts the outer edge of the forward end of the inboard screen, the rays will cross suitably.

E.—EXTRACT from the INSTRUCTIONS of 1887.†

The inboard screens should be so fitted as to prevent the red and green rays crossing too close to the ship. There are many ways of doing this: for example, the screen may be lengthened, or another board may be placed outside it (fig. 7); or a chock (equal in thickness to the distance between the inner edge of the lens and the side of the screen) may be secured to the fore end

* Identical rules are laid down in the corresponding paragraphs of the Instructions of 1884.

† Identical rules are laid down in the corresponding paragraphs of the Instructions of 1891.

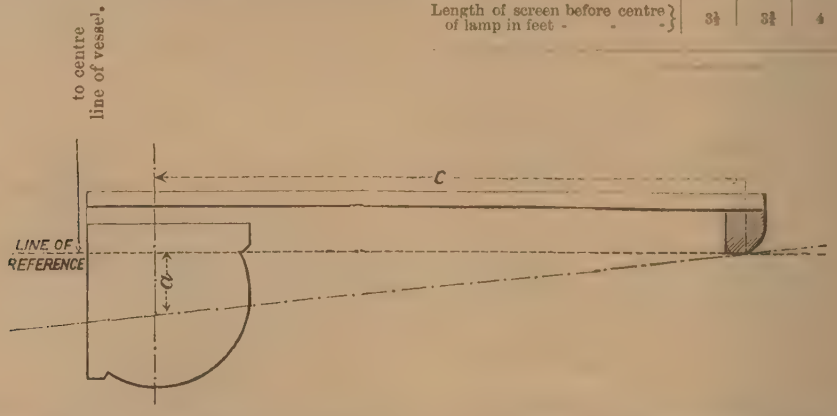
App. 1, Nos. 2 and 3.

of the screen (fig. 8); or the lamp may be so placed that the outside of the screen will come against the inner edge of the lens (fig. 9); or the screens may be so placed that the distance across the ship between their outer sides at the fore end shall be equal to the distance between the inner edges of the lenses of the two lamps (fig. 10).

As regards the distance before the lights where the rays cross, if the screens are fitted as shown in figures 7, 8, 9, or 10 of the instructions, *i.e.*, so that the line joining the inner side of the lens and the forward outboard edge of screen (or chock, if one is fitted) is parallel to the centre line of the vessel, or if the screens are fitted as in figure 6, the following will give the

For 40 feet beam where $b = 20$ feet.

| Distance $a$ in inches from Line of Reference to Point where most convergent ray cuts transverse central Line of Lamp. | Distance in Feet forward of Screen to the Point where ray crosses centre Line of Vessel. | | | | |
|---|---|---|---|---|---|
| 2 | 420 | 450 | 480 | 510 | 540 |
| 2½ | 336 | 360 | 384 | 408 | 432 |
| 3 | 280 | 300 | 320 | 340 | 360 |
| 3½ | 240 | 257 | 274 | 291 | 308½ |
| 4 | 210 | 225 | 240 | 255 | 270 |
| Length of screen before centre of lamp in feet | 3½ | 3¾ | 4 | 4¼ | 4½ |



distance in feet from *centre of lamp* to the point where a ray first crosses the centre line of vessel produced.

$$\frac{12bc}{a} + c$$

Where $a$ = distance in inches from the line through forward outboard edge of screen drawn parallel to the centre line of vessel, and the point where the most convergent ray cuts thwartship centre line of lamp. This ray is that which crosses the centre line of vessel at the shortest distance ahead.

$b$ = distance in feet between the line of reference and the centre of the vessel.

$c$ = length in feet of screen before centre of lamp.

or the distance in feet before the *forward edge of screen* to the point where the ray crosses the centre line of the ship is

$$\frac{12bc}{a}.$$

Thus, if always measured from the forward edge to the screen, the distance ahead where the ray from the lamp crosses the centre line varies directly as the beam and the length of the screen, but inversely as the distance $a$, the position of which is to be determined by actual inspection of the lighted lamp, and this fixes the direction of the most convergent ray of light.

For 20 feet beam where $b = 10$ feet.

| Distance $a$ in inches from Line of Reference to Point where most convergent ray cuts transverse central Line of Lamp. | Distance in Feet forward of Screen to the Point where the ray crosses centre Line of Vessel. | | | | |
|---|---|---|---|---|---|
| 2 | 210 | 225 | 240 | 255 | 270 |
| 2½ | 168 | 180 | 192 | 204 | 216 |
| 3 | 140 | 150 | 160 | 170 | 180 |
| 3½ | 120 | 128½ | 137 | 145½ | 154½ |
| 4 | 105 | 112½ | 120 | 127½ | 135 |
| Length of screen before centre of lamp in feet | 3½ | 3¾ | 4 | 4¼ | 4½ |

No. 3.—Case for the Opinion of the Attorney-General, the Solicitor-General, Sir Richard Webster, Q.C., Mr. Sutton, and Dr. Raikes.

The Merchant Shipping Act Amendment Act, 1862, section 25, provides as follows:

On and after the 1st day of June 1863, or such later day as may be fixed for the purpose by Order in Council the regulations contained in the table marked (C.) in the schedule hereto shall come into operation and be of the same force as if they were enacted in the body of this Act, but Her Majesty may from time to time, on the joint recommendation of the Admiralty and the Board of Trade, by Order in Council, annul or modify any of the said regulations, or make new regulations in addition thereto, or in substitution therefor, and any alterations in, or additions to such regulations made in manner aforesaid shall be of the same force as the regulations in the said schedule.

The Merchant Shipping Act, 1873, section 17, provided as follows:

"If in any case of collision it is proved to the court before which the case is tried, that any of the regulations for preventing collisions contained in or made under the Merchant Shipping Acts, 1854 to 1873, has been infringed, the ship by which such regulation has been infringed shall be deemed to be in fault, unless it is shown to the satisfaction of the court that the circumstances of the case made departure from the regulation necessary."

Copies of the Orders in Council and regulations made in pursuance of section 25 of the Merchant Shipping Act Amendment Act, 1862, are left herewith, and, as counsel is aware, the last of such Orders in Council dated the 30th of January, 1893, contains an addition to the regulations with reference to ships' side lights in order to explain Articles 3 and 15 of the regulations, and to remove doubt and misapprehension concerning the effect of such articles.

The following are copies of letters addressed to the Board of Trade by the Liverpool Steam Ship Owners Association:—

The Liverpool Steam Ship Owners' Association,
10, Water Street, Liverpool,
Sir, 7th February 1893.

*Side Lights.*

With reference to the Order in Council dated the 30th ultimo, that appeared in the "London Gazette" of the 3rd instant dealing with this matter, I am instructed to again urge upon you on behalf of my Association the importance of the Board suspending their action until this country is able to act in concurrence with the foreign countries who have adopted the international

regulations. In urging this course upon you my justification must be the extreme importance of the matter to shipowners in this country.

In considering whether or not the Order of the 30th ultimo merely explains Article 2, sub-section *d*, I would venture to draw your attention to the case of the "Fire Queen" decided by the late Mr. Justice Butt in 1887. In his judgment in that case the learned judge said: "I am strongly inclined to believe that the right "thing to aim at would be to adhere to the arc of 10 "points, starting from two points abaft the beam, and "to carry the light so as to allow it to be seen no further "forward than an arc of 10 points would allow. That "would leave, if it were exactly carried out and the "ship were motionless, a space in darkness right ahead "equivalent to the beam of the ship, but the lights "would not then be visible across the stem."

If Mr. Justice Butt's interpretation of the regulations is correct, then I would submit that it is obvious that the courts of the foreign countries who were parties to the making of such regulations will not be bound by the Order of the 30th ultimo. On the other hand, even if Mr. Justice Butt's interpretation of the regulations is incorrect, still the question of the proper interpretation to be put on the regulation is left in such doubt that it must be uncertain whether or not the foreign courts would adopt the explanation adopted by the Order of the 30th ultimo.

In the meantime the shipowner must be exposed to the risk of having claims which may amount to many thousands of pounds made on him in foreign countries in consequence of his non-compliance with the international regulations.

Apart from these considerations I would point out that before the regulations of 1880 were sanctioned, the foreign countries parties to the international regulations were consulted, and their approval obtained to the new regulations.

Having regard to these circumstances, on behalf of my Association I would urge upon you the re-consideration of the position in which the British shipowner is being placed by the act of the Board.

I have, &c.
(Signed) GRAY HILL,
Secretary.

The Right Hon. A. J. Mundella, M.P.
President, Board of Trade.

---

The Liverpool Steam Ship Owners' Association,
10, Water Street, Liverpool,
14th February, 1893.

SIR,

*Side Lights.*

I AM instructed by my Association to communicate with you in further reference to the Order in Council dated the 30th ultimo, having regard to the answer given by you in the House to Mr. Houston on the 10th instant.

May I again point out that the position in which this question stands is as follows:

Since the year 1863 until the Order in Council made on the 30th ultimo, Article 2, sub-section *d* of the Regulations for Preventing Collisions at Sea has always provided that a vessel's side lights should be so screened "as to prevent these lights from being seen across the "bow." This regulation has been adopted by:—

| | |
|---|---|
| Austria. | France. |
| Russia. | Belgium. |
| Netherlands. | Spain. |
| Germany. | Norway. |
| Chili. | Greece. |
| Sweden. | Denmark. |
| Portugal. | United States. |
| Italy. | |

The effect of the article has been repeatedly considered by the English courts, and in one reported decision, the case of the "Fire Queen," the English Admiralty Court has distinctly laid down that under the Article, the lights must be so screened as not to cross the line of the ship's keel projected ahead of the ship.

By the Order in Council of the 30th ultimo, the the Board of Trade, although in words purporting only to explain the meaning of Article 2, sub-section *d*, have in fact made an entirely new regulation, as the effect of their explanation is to require that the lights "shall "cross the line of the ship's keel projected ahead of "the ship at a reasonable distance ahead of the ship." This alteration has been made without apparently the

foreign powers, who were parties to and are bound by the original regulations, having been consulted in any way, certainly without their concurrence in the alteration having been obtained. App. I, No. 3.

On no previous occasion, so far as my Association is aware, has any material alteration been made in the regulations of 1862 without the concurrence of the foreign powers.

In the opinion of my Association, whilst it may be a matter of opinion as to whether or not the alteration proposed by the Board of Trade is one that should be adopted, there can be no question as to the importance of maintaining the international character of the Regulations for Preventing Collisions at Sea, and it is in the opinion of my Association greatly to be regretted that any steps should have been taken which tend to destroy the international character.

Apart from these considerations I would again draw your attention to the serious pecuniary risk to which the British shipowner is being exposed by reason of the alteration having been made without international sanction. In British waters the shipowner is bound to obey the Order in Council and will be held responsible for any disobedience to it, but in foreign waters it is equally clear that he will be held responsible for any disobedience to the international regulations. So long as Mr. Justice Butt's judgment stands it is impossible for the British shipowner to obey both at the same time.

Having regard to these circumstances I would again, on behalf of my Association, urge upon you the reconsideration of the position in which the British shipowner is being placed by the action of the Board, and the advisability of at once suspending the operation of the Order in Council until the concurrence of the foreign powers has been obtained to the alteration.

I am, &c.
(Signed) GRAY HILL,
Secretary.

The Right Hon. A. J. Mundella, M.P.

---

The receipt of these letters was duly acknowledged.

In March 1893 the Board of Trade issued a notice, of which the following is a copy:—

*Notice to Shipowners and Masters.*

*Screening of Side Lights.*

The Board of Trade desire to call the attention of shipowners and masters to the accompanying copy of a recent Order in Council of the 30th January 1893, explaining the regulations contained in the Order in Council of the 11th August 1884 as regards the screening of side lights.

No declaration for a passenger certificate is, after the 1st May next, to be issued to any vessel whose side lights are not screened as required by the Order in Council. The Board of Trade in the meantime accept no responsibility where the Order in Council is not complied with.

GEORGE J. SWANSTON,
Assistant Secretary,
Marine Department.

Board of Trade,
March 1893.

---

The following correspondence ensued:—

The Liverpool Steam Ship Owners' Association,
10, Water Street, Liverpool,
27th March 1893.

SIR,

*Screening of Side Lights.*

I AM instructed by my Association to communicate with you with reference to the notice to shipowners and masters (Handbill No. 120) that has recently been issued by the Board of Trade. From this notice the members of my Association understand that after the 1st May next no passenger certificate will be issued for any vessel whose side lights are not screened as required by the new Order in Council. In the opinion of my Association the result of making the new regulation effective as from the 1st May as against passenger vessels, but not effective as against vessels other than passenger vessels, and not effective as against foreign vessels, will be to send to sea at the same time vessels whose lights are screened on principles entirely different, and thus to enormously increase the risk of collisions at sea.

App. 1, No. 8.

My Association, in the interests of the British shipowners generally, trust that you will see your way to suspend the enforcement of the new regulation until you have got the approval of foreign powers to the alteration that such Order makes in the regulations of 1880 and 1884, and that the Board of Trade will not make the regulations until they have been so approved effective against only one class of vessels.

I have, &c.
(Signed) NORMAN HILL,
Secretary.

The Right Hon. A. J. Mundella, M.P.,
President, Board of Trade.

---

Board of Trade,
SIR, 11th April 1893.

WITH reference to your letter of the 27th ultimo, addressed to the President of the Board of Trade regarding the notice recently issued by this Department to shipowners and masters respecting the screening of ships' lights, I am directed by the Board of Trade to state that it is not the case that the regulations contained in the Order in Council of the 30th January last on the subject of ships' lights will be made effective as regards British passenger vessels only. All British vessels and all foreign vessels in British jurisdiction, whether such British and foreign vessels do or do not sail under the Passengers Acts, will be required to have their side lights screened in accordance with the regulations contained in the Order in question.

I am to add that steps have been taken to communicate the Order to foreign powers, and that the Board see no reason for postponing the enforcement of the Order beyond the date already referred to.

I am, &c.
The Secretary, (Signed) GEORGE J. SWANSTON.
Liverpool S.S. Owners' Association,
10, Water Street, Liverpool.

---

A further communication was received from the Liverpool Steam Ship Owners' Association, of which the following is a copy:—

The Liverpool Steam Ship Owners' Association,
10, Water Street, Liverpool,
SIR, 26th April 1893.

*Side Lights.*

IN further reference to the correspondence my Association have had with you with reference to this matter, I am now instructed to send to you herewith a copy of a case submitted under the instructions of my Association for the opinion of Sir Walter Phillimore, Q.C., and Mr. Joseph Walton, Q.C., with the opinion of these gentlemen upon the point submitted to them.

I should explain that with the other papers submitted to counsel was a complete copy of the correspondence.

Having regard to the strong opinion expressed by counsel my Association would again respectfully urge upon you the reconsideration of the whole question.

I have, &c.
(Signed) NORMAN HILL,
Secretary.

The Right Hon. A. J. Mundella, M.P.,
President, Board of Trade.

*The Liverpool Steam Ship Owners' Association.*

*Side Lights.*

*Case for the Opinion of Counsel.*

Herewith are sent—

Copy correspondence between the Association and the Board of Trade.

Print of the memorandum prepared by the association.

Copy of the London Gazette containing an Order in Council, dated the 30th January 1893, made under the Merchant Shipping Act Amendment Act, 1862.

The Liverpool Steam Ship Owners' Association desire counsel's opinion on the points arising on the correspondence and the printed memorandum that are sent herewith.

The President of the Board of Trade, in answer to the questions that have been put to him in the House of Commons, has repeatedly stated that the regulations contained in the Order in Council of the 30th January 1893 do not differ from but are only explanatory of the Regulations for the Prevention of Collisions at Sea contained in the schedule of the Order in Council of the 11th August 1884, and on this ground he has intimated that he does not consider it necessary to obtain the concurrence of the foreign powers who are bound by these regulations to the alteration.

On the Attorney-General being questioned in the House upon that point, the only answer he would give was that in the opinion of the naval advisers of the Board of Trade the Order in Council of the 30th January was only an explanatory Order, and did not make any alterations in the international regulations.

On these facts counsel will please advise:

1. Whether the regulations made by the Order in Council of the 30th January 1893 are merely explanatory of the regulations of 1884, or whether the Order in fact creates an entirely new rule as to the screening of side lights.
2. In either event counsel will please advise whether a British shipowner in complying with the Order of the 30th January 1893 will or will not be complying with Article 3, sub-section *d*, of the regulations of 1880 and 1884.
3. If counsel is of opinion that the shipowner in complying with the Order in Council of the 30th January 1893 will be acting contrary to the provisions of Article 3, sub-section *d*, of the regulations of 1880 and 1884, counsel will please advise whether a British shipowner will be held responsible for such non-compliance in the courts of the foreign countries who are parties to the regulations of 1880 and 1884.
4. Counsel will also please advise on the general questions raised in the correspondence.

*Opinion.*

1. The regulation of the 30th January 1893, Article 3 (*e*) is undoubtedly a new rule, the infringement of which by any vessel will cause such vessel, in case of collision, to be held to blame.

2. The new regulation seems to suggest that the words "across the bow" in Article 3 (*d*) means "across the bow of the ship itself." In our opinion this is not the correct construction of the words. We think that they mean the same thing as "across the line of the keel projected ahead." If this is so the new regulation is inconsistent with Article 3 (*d*). A shipowner who has his side lights fixed as required by the new regulation does not comply with the terms of Article 3 (*d*).

3. It must, however, be remembered as pointed out in the "Fire Queen," that a literal compliance with all the requirements of Article 3 is impracticable. What is required is a reasonable compliance. It is difficult to advise as to what view a foreign tribunal would take as to what is a reasonable compliance with the regulation. We think, having regard to the plain inconsistency in terms between the new regulation and Article 3 (*d*) that an English shipowner who has complied with the new regulation would be in danger before a foreign tribunal of being held responsible for a breach of Article 3 (*d*). Where, however, the foreign legislation does not include any provision similar to section 17 of the Merchant Shipping Act 1873, and the court has to consider whether the breach in fact contributed to the collision, the danger would probably not be serious.

4. We think that the Board of Trade would have accomplished what appears by the correspondence to have been their main object, viz., the prevention of excessive crossing of the lights by directing their surveyor not to pass side lights so fixed that the angle exceeded 4°. Such a regulation might have been made without creating the present difficulty. We may point out that a foreign vessel may be held to blame in the English Court for a breach of the new regulation, although such vessel has complied with the regulations which have been made binding upon her by the legislation of her own country with the concurrence of the British Government. It seems unfortunate that Article 3 should be made to say in one sub-section that the lights shall not be seen across, and in another that they shall cross at a reasonable distance ahead.

WALTER G. F. PHILLIMORE.
JOSEPH WALTON.

Temple,
April 22, 1893.

The above opinion having been submitted to Dr. Raikes, he wrote the following observations thereon:—

"Prior to the making of the Order in Council of the 30th January 1893, there certainly was, as the Order itself recites 'doubt as to the effect of Articles 3 and 15.' It was always open to argument that 'across the bow,' Article 3 (*d*), meant across the line of the keel projected ahead of the ship, and there has never been a judicial decision on the point so far as I have been able to ascertain.

"The case of the 'Fire Queen,' 12 P. D. 147, 6 Asp. M. L. C. 146, as a judicial decision at most held that under the rules then existing (1887) a vessel reasonably complied with the regulations notwithstanding her bow light was obscured to the amount of 2½° or 3° from right ahead of itself; there was no question as to its showing across the bow, whether inboard or as meaning the line of keel projected ahead of the ship, and the further observations of the learned judge are *obiter dicta*; the question of how Articles 3 (*d*) and 15 are to be read together and not argued before him.

"It must be clear that the case of the 'Fire Queen,' though doubtless correct as to its decision in itself, showed what dangerous latitude the rules allowed as to the screening of lights. Two sailing vessels, with lights screened as the 'Fire Queen's' were, might be meeting 'end on' or 'nearly end on' and neither see any light of the other before the vessels were actually in collision. The judgment discloses a possible weak place in the rules which the Order in Council heals without inconsistency.

"It may indeed be said that the whole judgment, so far as it held that the lights reasonably complied with the regulations was *obiter*, for the learned judge finds as a fact that the obscuration could have had nothing to do with the collision, and that finding was sufficient to decide the case (Eastern S.S. Co. *v.* Smith, the Duke of Buccleuch (1891), A. C. 310, and cases there cited).

"I have already said that prior to the recent Order in Council there was a doubt, and the existence of the doubt called for the Order in Council, but I think it is not difficult to show, with all possible deference to the contrary opinion as to the true construction of the rules of Sir Walter Phillimore and Mr. Joseph Walton, that across the bow meant across the bow of the ship itself, and not across the line of the keel projected ahead of the ship.

"In the first place, when coloured lights were introduced for steam vessels in 1852, there was no provision for the place where they were to be exhibited, and as a matter of practice they were, I believe, shown right forward, one at each knight head, or on each side of the stem; this position would, so far as I can see, even now comply with the regulations, but the proviso was inserted that wherever shown they were not to show across the bow. Nothing would have been easier or more natural than to say they were not to show across the course of the vessel or on the other bow if that had been meant, but the other phraseology was used. The French version throws much light on the point, as in describing the arc over which the light is to show it says, 'un arc horizontal de 10 quarts du compas qui est compris entre l'avant du navire (ahead of the ship) et 2 quarts sur l'arrière,' and this phraseology is still preserved; the language used is all the more pointed when it is noticed that in speaking of the mast head lights the words 'du navire' are left out as there unnecessary, the expression being simply 'depuis l'avant jusqu'à 2 quarts en arrière,' which shows that the words were intentionally inserted with regard to the side lights. The French version is the only really important one to be considered, as that and the English version were issued together as of equal authority, and the other nations simply translated them. It may, however, be meant, and that both the Spanish and the Portuguese translation adopt words referring to the head of the ship.

"After some time it was found that seamen were giving too wide an interpretation to Article 15 in its original form (Article 13 of the rules of 1863), and that the constant use of port helm in cases where vessels were in fact crossing or starboard to starboard was leading to collisions, and the explanation of that Article was given by the Order in Council of July 1885 and subsequently in the Rules of 1897, incorporated with the Articles itself. The addendum clearly contemplates that lights should be seen together when the vessel carrying them is end on or nearly so, *i.e.*, that they both should be seen ahead of the ship herself and not merely each ahead of itself when they could not be seen together at all, but it goes further and makes the seeing of both lights together at night the correlative of the ship being seen to be nearly end on by day. App. I, No. 3.

"At the time this addition to the rules was made there can be no doubt that the practically universal plan was to carry the lights at the side of the ship, and it is obvious, both from practical considerations, simple experiments, and elementary mathematics, that if lights so carried are to be seen ahead of the ship itself, *i.e.*, on the line of the keel at any distance, they must at any further distance be seen across the line of the keel. If this is not so, the latter part of the second clause of the addendum to Article 15 has no meaning, and that is a view abhorrent to the law. If a statute is ambiguous, but one reading conveys an intelligible meaning and the other does not, it is a well recognised principle of interpretation that the former must be adopted; Maxwell on 'Interpretation of Statutes,' p. 242 (ed. 1883), and cases there cited. For all these reasons, I am of opinion that the first part of the new Order in Council, though a new rule in the sense that it has not previously been formulated in words, is not new in the sense of adopting a new principle of construction, though it does bring a person infringing it to a substantial degree under the provisions of section 17 of the Merchant Shipping Act 1873, which might not previously have been the case if the dicta in the 'Fire Queen' are to be taken as an accurate statement of the law.

"It must further be observed that Article 3 requires the light to be uniform over 10 points from right ahead to 2 points abaft the beam, *i.e.*, that over that arc it shows its full force; it does not say in terms that it may not show even its full force somewhat further, and I have endeavoured to show that to show its full power right ahead of the ship it must at some distance ahead of the ship show across the line of the keel; and if I am right in my reading of the rule as it stood before the last Order in Council, there is no breach of the regulations in its so doing provided it does not show across the bows inboard. If all vessels carried the lights at or forward of the middle of the ship this proviso might seem needless, but it is to be remembered that the rules are international, and that very many foreign, and indeed not a few British colonial vessels carry their lights right aft, and in the case of a vessel of 30 feet beam, where the lights are carried 250 feet aft, an angle of 4° will just about cut the stem, and against any greater convergence than this it was necessary to guard, and that is in my opinion a reasonable interpretation of the rule as it originally stood, and a good reason for it, *i.e.*, that the inboard screens are to be so fitted that both lights shall always show with their full power right ahead of the ship at a reasonable distance ahead, but shall never cross inboard of the ship. The rule does not say that they shall show only right ahead, and indeed it is impossible that they should do so if from any point on the side they do show right ahead of the ship. Beyond the arc over which the full power of the light is seen, there must be a further arc over which the light is seen with gradually diminishing intensity, unless the light emanated from an actual point, which is, whilst lamps with wicks are used, an impossibility.

"The instructions to surveyors contained in the second part of the Order in Council will not give the full force at 4°; this will not be arrived at till all the direct rays are seen, that is, till the spectator is in a line with the inner edge of the wick, and the foremost end of the screen probably about 2° or 2½°, but I understand the angle has been fixed on as one found by practice to be most common and best adapted to prevent collisions, and required the least possible alteration of existing lights and screens whilst establishing for the future uniformity of practice. It may, of course, be a question whether that angle which has been found to answer well hitherto is too broad considering the present size and speed of ships, and especially in narrow waters, but for the reasons I have stated, especially from the French version of the rules and the conditions necessary to bring the side lights into conformity with that version, I do not think that any foreign court could hold a vessel to blame for having her lights screened as directed by the new Order in Council, but it is of course impossible for anyone to say what view a court, especially as is generally the case abroad, a court not specially cognizant of the subject and unassisted by nautical experts, may take

APP. 1, No. 3.

"I do not think any country, except Sweden and Denmark in the new maritime law common to both States, have any provision analogous to section 17 of the Merchant Shipping Act, 1873.

"I do not see that the form of rule suggested in the joint opinion of Sir W. Phillimore and Mr. Walton would be in any way beneficial. A vessel under it might have her lights screened up to 4° and be in accordance with the English rule, and would in respect to foreign tribunals be in the same position as under the existing Order in Council, whilst if the 'Fire Queen' is to be taken as law, she might still have her lights dangerously divergent.

"F. W. RAIKES.

"7, King's Bench Walk,
"Temple, E.C.
"May 9, 1893."

---

It may be observed that if, as suggested in paragraph 4 of this opinion, the Board of Trade had instructed their surveyors not to pass side lights so fixed that the angle exceeded 4°, uniformity would not have been attained. In the same ship one light might then have been screened to 0° whilst the other was screened to an angle of 4°.

Sir Digby Murray, in writing unofficially to Sir Charles Hall upon this subject, enclosed for his information the following memorandum:—

MEMORANDUM showing the angle of convergence of the side lights, supposing them to be screened in the ordinary manner, *i.e.*, the screens extending forward in a line parallel to the keel, the outer surface of the screen touching the inner face of the side light, and with its length measured from the centre of the flame.

Length of screen, 600 ft.

Distance from outer edge of screen to outer edge of wick, 10 inches.

Angle of convergence; 0° 4′ 35″.

Worked example—

| | | |
|---|---|---|
| Log 7200 (+10) = | | 13,857,332 |
| Log 10 | | 1,000,000 |
| | | 12,857,332 |
| | ° ′ ″ | |
| Log tangent A. | 89 55 25 | |
| Angle B. | 90 0 0 | |
| Angle C. | 0 4 35 | |

D. MURRAY.

| Length of screen forward of light in inches. | Angle corresponding to a distance of 10 inches measured from outer edge of screen to outer edge of wick. | Angle corresponding to a distance of 11 inches measured from outer edge of screen to outer edge of wick. |
|---|---|---|
| | ° ′ ″ | ° ′ ″ |
| 36 | 15 32 0 | 16 59 0 |
| 72 | 7 54 30 | 8 42 0 |
| 108 | 5 17 30 | 5 49 0 |
| 144 | 3 58 30 | 4 22 0 |

If Sir Charles Hall and Dr. Raikes are in error in their interpretation of Article 3 (*d*), how does Sir Walter Phillimore reconcile the words "at least 3 feet forward "from the light, so as to prevent these lights from being "seen across the bow" with the above angles?

A print of a further Memorandum by Sir Digby Murray upon the Regulations as to side lights is also left herewith for counsel's information.

Since this case was prepared, the United States Government have intimated their agreement with the new Order in Council, subject to the decision of Congress.

Counsel are requested to advise—

1. Whether the words in Article 3 (*d*) "across the bow" mean across the bow of the ship itself, or whether these words can be construed to mean across the line of the keel projected ahead?
2. And generally upon the opinion of Sir Walter Phillimore and Mr. Joseph Walton.

*Opinion.*

1. With respect to the question whether the words in Article 3 (*d*) of the Regulations "across the bow" mean across the bow itself of the ship, or whether they can be construed to mean across the line of the keel projected ahead, if the language of the sub-article is considered separately, apart from the subject matter of sub-articles (*b*) and (*c*), and also from the provisions of Article 15, of the same regulations, then we think that the words in question are susceptible of either meaning. We are of opinion, however, that in order correctly to interpret the words "across the bow" these provisions of Article 3 must be read together with those of Article 15, and their subject matter examined, and thus considering the two Articles we are of opinion that the expression "across the bow" in Article 3 (*d*) means across the bow itself of the ship and does not mean across the line of the keel projected ahead.

Our opinion on this point is principally based upon the following considerations:—

(*a*) Article 15 is amongst other matters directed to the critical position of two ships meeting end on, or nearly end on, and provides that under such circumstances both lights shall be seen at the same time, and Article 3 (*b*) and (*c*) contemplate that the red and green lights shall show their light ahead of the ship itself.

(*b.*) The construction we have placed upon the words "across the bow" does not conflict with either of these provisions, but it is in harmony with and reconciles both of them.

(*c.*) If these words are interpreted to mean across the line of the keel projected ahead, then the lights would have to be screened so as to prevent the red and green rays crossing the line. Such a construction, however, would be repugnant to both Articles for unless the red and green rays cross the path of the ship it would be impossible to see both lights at the same time in positions in which it was undoubtedly intended that both lights should be seen, and further, it would be impossible for a side light so screened to show a proper or effective light ahead at all.

(*d.*) The language of Article 3 (*d*) itself does not conflict with the view we have expressed, for the earlier part of the Article clearly refers to the ship itself, and in our opinion such words as "across the bow" would not have been used had it been intended to refer to the line of the keel projected ahead.

Moreover the framers of this Article could not have supposed that anything like a 3-foot screen could prevent the rays of the side lights being seen across the path of the ship, or if the lights were carried on the after part of the ship, could do more than prevent them from being seen across the bow itself of the ship.

We may add that the practice followed by the Board of Trade for many years in the instructions given by them to their surveyors as to the fixing and screening of lights appear to have corresponded practically with the opinion above given.

2. With respect to the regulations contained in the Schedule to the Order in Council of the 30th January 1893, we are of opinion, for the reasons already given, that the first of such regulations correctly interprets Article 3 (*d*) with respect to the meaning of the words "across the bow," and its direction that the lights must be "fixed and the screens fitted so that the rays from the red and green lights shall cross the line of the ship's keel projected ahead of the ship at a reasonable distance ahead of the ship" merely expresses what is necessarily and properly involved by such interpretation.

We are accordingly of opinion that this Regulation is merely explanatory of existing Regulations, and that an English shipowner by obeying it would not thereby involve himself in risk before a foreign tribunal.

As to the second of such Regulations, it directs a specific angle of 4° to which the lights are to be fixed and screened. The question whether the Regulation is a new Regulation or not is one of some difficulty, but on the whole, if the angle substantially carries out and gives effect to the instructions which the Board of Trade for many years have given to their surveyors with respect to the fixing and screening of lights, and that compliance with the instructions of the Board of Trade has not given rise to trouble in the past, and assuming that by adopting such angle the rays of the light will cross the path of the ship at a distance ahead of the ship that has hitherto been found safe, we are of

opinion that the regulation embodies no new principle, and that an English shipowner by obeying it would not thereby involve himself in any appreciable risk before a foreign tribunal.

3. We are of opinion that in order to prevent any difficulty arising from these regulations the Order in Council should be communicated to the foreign Governments, and their assent thereto obtained with as little delay as possible.

Royal Courts of Justice,
12th August 1893.

No. 4.—Report of the Rule of the Road Committee.

To the Right Honourable A. J. Mundella, M.P.,
President of the Board of Trade.

Sir, December 8, 1893.

We have considered the letters received by the Board of Trade from Foreign and Colonial Governments, and from certain British Shipowners' Societies, in regard to the proposed alterations of the International Regulations for Preventing Collisions at Sea, as recommended by the Washington Marine Conference, 1889, and as subsequently modified by the Committee appointed in July 1890, to consider the recommendations of that Conference.

We have also heard representatives from the Shipowners' Societies on the various points raised by them, and we have especially considered the objections made to Articles 15, 21, and 28.

We see no reason to recommend any alteration in the rules submitted by the late Committee in their report, dated June 22, 1892, and we entirely concur in that report, which has received the general approval of the foreign powers.

We witnessed experiments in the screening of sidelights at Shoeburyness on the nights of the 12th and 13th October, and we have carefully considered whether any alteration is desirable in the present regulations as to such screening.

We consider that the rule now in force under the Order in Council of January 1893 merely confirms the previous practice of the Board of Trade, and that the method of measurement now laid down is better calculated to ensure uniformity of screening, and as this practice has up to the present time worked well, we see no necessity for the rule being altered. App. 1, No. 4.

At the same time we desire to point out that no strict uniformity of the angle at which the full strength of the lights is in practice visible is possible so long as a great variety of patterns of lamps are in use, and in view of this fact, as well as of the great improvements which have been and are being made in the construction of lamps, and in the power of illuminants, and of the great increase in the size and speed of ships, we think that the Board of Trade should, in certain cases, upon the request of the shipowner, have power to allow the angle of screening to be reduced to 3°, or in special cases to even less than that angle.

We wish to acknowledge the valuable assistance which we have received from our secretary, Mr. Hipwood, who has, by his industry and ability, materially lessened our labours.

We are, &c.

C. Hipwood,
Secretary.

*Separate Report by Mr. Watson.*

Sir,

In signing the foregoing report, I do so subject to my dissent being again recorded to the addition of the words "and speed" to Article 21, as I consider that the very strong opinions expressed against the addition by the shipowners of this country and others fully bear out the view I felt it my duty to put forward on the subject in my former separate report.

I am, &c.
(Signed) William Watson.

The Right Hon. A. J. Mundella, M.P.
December 8, 1893.

* Subject to separate report.

## APPENDIX No. 2.

*Papers handed in by Sir D. Murray.* App. 2, No. 1.

No. 1.—Instructions to Surveyors as to Ships' Lights and Fog Signals, issued in January 1892.

*General.*

1. The following are the revised instructions issued by the Board of Trade to their surveyors respecting lights and fog signals, and supersede Circular No. 526 and paragraphs 72 to 96 of the "Instructions as to the "Survey of Passenger Accommodation, Master's and "Crew Spaces, Lights and Fog Signals."

rtance spec-

2. The Board of Trade attach great importance to the inspection of the lights referred to in the Regulations for Preventing Collisions at Sea, and regard it as one of the most important duties intrusted to the surveyors. At their request, the Commissioners of Customs, with a view to the enforcement of the Regulations, have instructed their outdoor officers to at once report to the surveyors any cases of infringement of the rules which may come under their notice. But the surveyors themselves should take every opportunity of inspecting the lights of vessels lying within their districts, more especially in cases where they have reason to believe that the Regulations are evaded, either wholly or partially; and whenever they are called upon to survey crew spaces, or to do anything on board a ship, they should inspect the lights and fog signals under the Acts.

Upon visiting a vessel for the purpose of inspecting her lights and fog signals, the surveyor should first inquire of the master for the certificate of inspection, *See* para. 4.

If the master produces the certificate in question the surveyor should compare the particulars of the lanthorns and screens, and their position as given in that certificate, with the description and position of the lanthorns carried on board. He should also inspect the fog signals on board.

If the surveyor finds that any particulars, as stated on the certificate, are not in accordance with the state of things on board, he should withdraw the certificate, and when all is in accordance with the Regulations, he should make an indorsement of the fact thereon and return it to the master or owner. A new certificate must not be issued in such a case.

As to detaining ships.

3. In cases in which lights and the means of making fog signals are not fitted and provided in accordance with the Regulations for Preventing Collisions at Sea, the surveyor making an inspection should be careful to fill up one of the forms supplied for the purpose, specifying the additions or alterations required, and give it or send it by post to the owner, master, or agent. He should point out to owners and masters the necessity of a strict compliance with the Regulations, and he should do all in his power to prevent unnecessary delay or inconvenience. A report on the form supplied for the purpose is to be sent at once to the collector of customs, who will, under sect. 30 of the Merchant Shipping Act Amendment Act, 1862, refuse

ART. 2, No. 1.

either (1) to grant the vessel a clearance or (2) to allow her to proceed to sea until he receives from the surveyor a report on the proper form that the Regulations are complied with; but the surveyor should be careful to use discretion in cases involving the detention of vessels for non-compliance with the Regulations as regards the lights and fog signals. He need not in all cases detain the ship. For instance: (*a.*) When the vessel is not about to leave the United Kingdom; (*b.*) When there is no reason to apprehend delay, or to doubt the good faith of the owner or master in carrying the Regulations, &c. into effect.

If the vessel should afterwards leave the port for another port also within the United Kingdom, before the surveyor is satisfied that the requirements have been complied with, he should be careful to communicate with the surveyor of the district or port to which the vessel is about to proceed or has proceeded, at the same time forwarding to him a statement of the expenses which have been incurred on account of the vessel, and giving notice that a fee is due in accordance with the Regulations in addition thereto.

Defects, when made good, certificate to be given.

4. When the additions or alterations required and notified to the owner have been made, and the surveyor is satisfied on further inspection that the Regulations are complied with, a form supplied for the purpose should be filled up and sent to the owner or master, and when the expenses named on the forms have been paid the surveyor should send to the collector a certificate under his hand (as required by the Act) on the proper form, and should fill up and deliver or send to the owner, master, or agent a certificate of inspection, a copy of which should immediately be sent to the Board of Trade, and also entered in the office light-book, with the individual surveyor's rotation number for light certificates. This rotation number should be entered on the original certificate as well as on the copy sent to the Board of Trade.

Regulation lights only to be carried.

5. Complaint has been made to the Board of Trade that certain sea-going steam ships have infringed the Regulations by carrying coloured light signals, used for steering and other purposes, which are not mentioned in or authorised by the said Regulations for Preventing Collisions at Sea. The carrying of any lights other than the lights prescribed by the said Regulations for Preventing Collisions at Sea is a distinct breach both of the provisions of the Merchant Shipping Act Amendment Act, 1862, and of the said Regulations, and will subject the offenders to the penalties and liabilities imposed by the said Act, which will be strictly enforced.

Lights, &c. of foreign vessels.

6. The surveyors have undoubtedly the right to inspect the lights, &c. of foreign ships within British jurisdiction, and in cases in which any surveyor has reason to believe or discovers that the lights of a foreign ship are imperfect, or the screens improperly placed, it is his duty to inspect them, and he should point out to the masters or the agents, if on board the vessel, when they are not in accordance with the Regulations, and it is the surveyor's duty to report to the Board of Trade when he finds foreign vessels' lights are not in accordance with the Regulations. The Board will then give such directions as may be considered best.

*Side Lights.*

7. The following instructions are not intended to be retrospective so far as lights previously fitted are concerned, excepting that the angle (4°) to which the lights are to be screened is always to be insisted upon, but surveyors are desired to use their influence with both owners and lamp-makers to induce them to comply with these instructions, especially as regards the colour of the glasses and the vertical divergence of plano-convex and dioptric lenses.

Lanthorns.

8. Surveyors can only insist on the lanthorns being of such a character and so fitted as to comply with the Regulations, but the following remarks may assist them in forming their judgment.

The width of the back and sides of the lanthorn should not be less than 9 inches, and their height should not be less than 11 inches.

The passages for the admission of air to the interior of the lanthorn should have ample area, and be so arranged that the flame of the lamp will not be extinguished or caused to smoke by the wind or motion of the vessel in rough weather. The lanthorn should be constructed in such a manner as to preclude the possibility of spray or broken water obtaining access to its interior in such quantity as to in any way interfere with the efficiency of the light.

The arm or bracket by which the lanthorn is clamped to the screen should not be less than $\frac{5}{8}$ inch in thickness by 2 inches in breadth; it should be a fairly good fit in the socket of the lanthorn, and be secured in such a manner that the tightening of the clamping screw will bring the side of the lanthorn parallel with the side of the screen. The clamping screw should be brass, T-shaped, and not less than $\frac{5}{8}$ inch in diameter. Or else, which is preferable, the lamp should be cleated to the screen top and bottom.

Lenses.

9. The lenses should be made of crown or flint glass, highly polished, and free from air-bubbles or other visible defects. Plano-convex and dioptric lenses should be made as thin as practicable consistently with efficiently and durability.

In order to insure the light being equally visible at all the required angles, it is desirable—

(1) that the lens should be the arc of a circle, and

(2) that the radius which describes it should be measured from the centre of the flame, so as to insure the latter being horizontally equidistant from every part of the lens; the length of the radius may be ascertained as follows:—

Measure the chord of any portion of the arc and the versed sine corresponding to that chord, when the following formula will give the length of the radius:

$$\frac{a^2}{v} + \frac{v}{2} = r.$$

Where $a$ = half the chord.
,, $v$ = the versed sine.
,, $r$ = radius.

The lens should embrace an angle of not less than 120°, and its height must in no case be less than the length of the radius.

The curvature of the outer face of plano-convex lenses and of the respective parts of the outer face of dioptric lenses should be arranged to give the desired concentration of the rays of light, subject to the condition that the light must be visible in a clear atmosphere on a dark night at a distance of at least one sea mile, when the lamp is heeled 20° either above or below the horizontal plane.

In sailing vessels and fishing smacks, from 10° to 15° would be sufficient, but as there is no difficulty in manufacturing lamps which shall have a vertical divergence of 20° and still show the distance required by the Regulations, it is desirable they should all be uniform in this respect.

Lenses coloured throughout absorb and consequently waste much of the light, and even those having a film of colouring matter over the inside face are frequently not as satisfactory as is desirable.

The surveyors should discourage the use of lenses coloured throughout, and when opportunity offers call attention to the obvious superiority of white lenses with coloured glass slides placed behind them.

When, however, the distinctive colouration is produced in this manner, suitable means should be provided for keeping the slide in its proper position, and for preventing the door of the lanthorn from being closed when the slide is displaced.

In some lamps these slides are fixtures, and the lens is hinged on the outside of the lamp so as to admit of both the slide and the lens being properly cleaned; the lens is also so fitted as to enable a current of air to pass between it and the slide. These lamps have given a very good result when tested at Shoeburyness; whether they succeed in practice it will take time to determine, but the fitting appears to be a very desirable one.

Colour.

10. The colour is a matter of very great importance, and the Board of Trade will send to each district samples of red and green glass, of two different tints. Slides of the same tint as either of these standards or of any intermediate tint may be regarded as satisfactory.

Corrugated lenses.

11. The attention of the Board of Trade has been called to the fact that a number of vessels use for side, masthead, and anchor lights, lenses having vertical corrugations or ridges on their inner surfaces. The effect of these corrugations is to cut up and obstruct the light and to rob the coloured lights of their distinctive colour when seen from certain positions. All these defects are objectionable in the case of lenses of coloured side-lights, and such lenses should not be passed.

*When sidelights are hung in gimbals with fixed screens the points of support should be in the same horizontal plane as the centre of the lens. When as is preferable they are fitted so that both screens and sidelights adapt themselves to the motion of the ship they should be fitted as shown in the above drawing. It is not intended the screen should be clamped in a fixed position unless the quick uneasy motion of the Ship renders this necessary.*

Wyman & Sons, Lt.Lith, 63, Carter Lane 6213-5 94

12. The cistern of the lamps should contain sufficient oil to last for at least 12 hours; it should not intercept any of the rays that would otherwise fall on the lower half of the lens, and its height should be such that the most luminous part of the flame will be level with the centre of the lens. The centre of the wick, or system of wicks when there are more than one, should coincide with the centre of the curvature of the inner face of the lens; and the base of the lamp should be so arranged, constructed, and fitted in the lanthorn as to render it practically impossible for the lamp to be accidentally or carelessly placed in, or to shift to, any position other than that which it would occupy when the foregoing conditions are fulfilled.

When two lamps, one for paraffin and the other for colza, are supplied with a lanthorn, the base plate of the lamps should be alike, and should occupy one and the same part of the lanthorn when the lamps are in their proper position. Lanthorns with means for placing the lamps at different heights should not be passed. The same lamp should not be passed for both paraffin and colza.

13. The wicks of paraffin lamps should not be less than 1 inch, and those of colza lamps not less than $1\frac{3}{4}$ inches in breadth. The wick-holder should be placed in the position of greatest efficiency, and means should be provided for preventing it from being accidentally or carelessly put in, or moved to, any other position.

The objects of this requirement are twofold, viz. (1) to preserve the efficiency of the lamp and (2) to insure the constancy of the angle at which the most divergent ray crosses ahead of the vessel. The wicks of anchor lights should not be less than $1\frac{1}{4}$ inches broad for oil and $\frac{3}{4}$ inch for paraffin.

14. When lamps are fitted with glass chimneys, these should be of plain white glass of the best quality and form, and there should be at least five spare ones on board for each lamp carried.

15. A substantial metal spherical reflector, silver plated and highly polished, should be fitted to each lamp, its horizontal axis should be in the same plane as the horizontal axis of the lens, the radius which describes the arc should be measured from the centre of the flame, and its length ascertained in the same manner as that of the lens, *i.e.*,

$$\frac{\frac{a^2}{v}+v}{2}=r.$$

If these instructions are complied with, the centre of curvature of the lens, the centre of curvature of the reflector, and the centre of the flame will be in the same line, both vertically and horizontally.

There is considerable difference of opinion amongst lamp-makers as to the most desirable size for reflectors, but they should not be so small that a line drawn from any part of the lens through the centre of the flame should fail to fall on its surface, and they should never be so large as to intercept any of the direct rays falling on the lens.

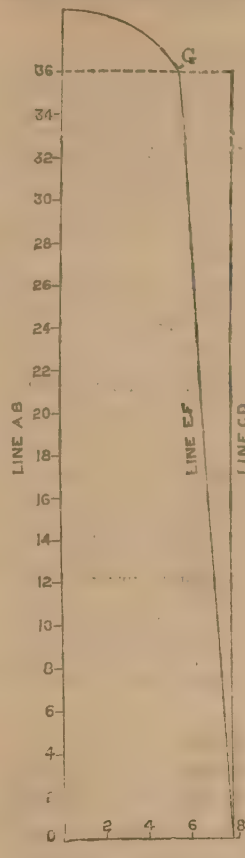
Means should be provided for preventing the lamp from being placed in the lanthorn with the reflector shipped, but not in its proper position.

16. Side-lights are always to be screened to an angle of 4° and are to be fitted as follows, excepting when in turrets, in which case it may be thought desirable so to arrange the screens as to dispense with chocks, *see* Plate II. When the screens are fitted as in Figs. 3 and 4, Plate III., the outer wall of the screen is to be considered as the chock.

In screens fitted previously to the issue of these instructions which exceed 36 inches in length, the distance at G from the line C D will be the length of the screen in inches × ·07.

When the screens are of wood, they should be well seasoned, and not less than $1\frac{1}{4}$ inches in thickness; the chock should be at least 2 inches in thickness, and rounded off, as shown in Figs. 1 and 2, Plate III.

The screens are never to be secured to the rigging except in the cases referred to in paragraph 20; when the screens are attached to movable davits or to outriggers extending outwards over the sides of the vessel they should be fitted with stop pins or distance rods, so contrived and arranged that when the stop pins are in their places the screens will be parallel with the middle line of the vessel. When the davits or stanchions for supporting the screens go through the top-gallant or main rail they should be carried down into sockets on the covering board or water-way, and have a nut or cotter under the rail to keep them in position.



Line A B represents the outer surface of screen, which is always to be 36 inches in length measured from a line passing transversely through the outer edge of wick. The screen and the measurement must be in a line parallel to the keel.

Line C D is a line drawn parallel to A B at a distance equal to the distance between the outer edge of the screen and the outer edge of the wick.

Line E F is a line projected from the outer edge of the wick at an angle of 4° measured from a line C D parallel to the vessel's keel.

Its distance from the line C D at G will always be 2·5 inches. Its distance at G from the line A B will always be equal to the required depth of the chock. The diagram represents the starboard lamp.

The screen should be so placed that the lights as screened to an angle of 4° will not be obscured by any of the fittings of the vessel, such as catheads, boats, boats' davits, sails, rigging, &c., or by passengers or crew moving or standing about forward of the lights. To insure this, the lights should be placed as far forward as practicable, and in vessels of very fine entrance where it may not be possible to carry them far forward, great care should be taken that the rays are not thrown so far inboard that persons can intercept them, remembering that the waterway main rail and stanchions are some protection. If the lights are of a sufficient height above the deck to protect them in this respect, no exception need be taken, otherwise either their height should be increased or they should be placed on properly constructed outriggers at the necessary distance outboard of the vessel. Lighthouse towers should be carefully noted in this respect, and in the case of new vessels any requisite alterations should be suggested by the surveyors before they are too far advanced.

Towers.

17. Towers should be as far forward in the ship as may be practicable, and if they will not then comply with the foregoing conditions their height must be increased until they do.

Their windows should be made of thin white glass of the best quality; they should be of such length and height as to admit of the lights showing in the manner required by the Regulations.

Windows consisting of two or three panes may be passed if the mullion or mullions are set at an angle of 45° from the vertical and do not exceed $\frac{3}{8}$ of an inch in width.

To enable the side lights in towers to show the two miles required by the regulations, it is probable they will require to have greater illuminating power than those carried in the ordinary manner.

Gimbals.

18. When side lights are hung on gimbals, the points of suspension of the latter should be in the same horizontal plane as the centre of the lens, in order that the angle at which the most divergent rays cross each other may be practically constant.

Oscillating screens.

19. The oscillating screens shown in Plate V. are considered preferable to gimbals, except for vessels in which the change of fore and aft trim is exceptionally

APP. 2, Nos. 1 and 2.

great. When the lamps are carried either by gimbals or oscillating screens the concentration of the lenses may be carried to a greater extent than is thought desirable for fixed lamps.

Lights in the rigging.

20. When trawlers and other sailing vessels whose gross registered tonnage does not exceed 80 tons cannot with safety and convenience of working carry their side lights on stanchions, they may be carried in the rigging, provided the surveyors are satisfied that they are so fitted as to show the lights for the distance and in the direction required by the regulations. This is not to be allowed in the case of steamers, and surveyors are to do their best to insure the side lights of all vessels of 200 tons or over being carried well forward of the midship section of the ship.

Vessels to be detained unless lights show as required by the Regulations.

21. In the event of the master or owner neglecting or refusing to alter the position of the lanthorns in such a way as to enable them to comply with the Regulations, the surveyor or inspector may report the fact to the collector of customs for the purpose of stopping the ship, and such collector may refuse to grant the vessel a clearance under section 30 of the Merchant Shipping Act Amendment Act, 1862, until he receives a report from the surveyor or inspector to the effect that his requirements have been complied with.

Consequences of altering lights when surveyor has passed them.

22. If after a vessel has been passed by such surveyor or inspector as carrying lanthorns and lights properly constructed and fixed, the master fixes them in such a position that they may be or are obscured so that they are not under all circumstances visible for a distance of two miles from right ahead to two points abaft the beam, on the respective sides, as required by Article 3 read in connexion with Article 24 of the Regulations, such master will be guilty of a misdemeanor under section 27 of the Merchant Shipping Act Amendment Act, 1862.

*Mast-head Light.*

Mast-head light in steamers.

23. The surveyors are to be careful to see that every steamer has fittings for the lanthorn for the white light "at the foremast-head," or elsewhere in front of the foremast-head on an independent stay, fitted with a fork and a piece of metal tube running up the stay to carry the fork; and secondly, to see that the light will show for the distance and in the direction required by the Regulations. Surveyors are not to advise owners how to arrange or modify sails, but are to decline declarations if the Regulations are not complied with. The surveyors are, if they think it necessary, to see the sails set. They are to go aloft to the mast-head in all cases before they give their declarations. Where a surveyor is from any cause unfit or unable to go aloft himself, he should not give a declaration unless one of his colleagues goes aloft for him and in his presence.

The rules regarding the wicks, wickholders, and position of the luminous part of the flame of side lights apply equally to mast-head lights.

*Electric Lights.*

Electric side and mast-head lights.

24. The Board of Trade are advised that ships' electric side and mast-head lights are not contrary to the International Regulations for Preventing Collisions at Sea, provided they are so constructed, fitted, and arranged as to show for the distances and in the directions and over the arcs required by the Regulations. But in all cases where the electric light is so fitted, it is the duty of the Board's surveyors to see that oil lamps for use in case of failure of the electric system are also provided and comply with the Regulations.

The power and character of the mast-head electric light should not be such as to give it the character or appearance of a shore light. Too strong a white light may, in the opinion of the Board of Trade, often be misleading, and therefore a source of danger to ships seeing it.

The preceding rules, &c., regarding the lenses, reflectors, screens, and screening of ordinary side lights, apply equally to electric lights.

---

No. 2.—SUMMARY of REPORTS by the PRINCIPAL OFFICERS of the BOARD OF TRADE, as to the ANGLE to which SIDE LIGHTS were screened prior to being re-screened in accordance with the INSTRUCTIONS of 1892.

**Leith District.**—Many found screened to 4°; others vary slightly, the angle being greater than 4° in some cases, and less in others. The rule appears to ensure uniformity not to cause change.

Reports by individual surveyors:—

*Mr. Lewis.*—In some cases no alteration required. In others angle was over 4°.

*Mr. Paxton.*—In many cases angle was 4°, in others it was either over or under 4°.

*Mr. Peacock.*—Nearly all screens approximately comply with the 4° rule. Where alteration has been required, the angle has generally been diminished.

*Mr. Wilkins and Mr. Barnet.*—In many cases only slight alteration required, and in these the angle was invariably diminished,

**Shields District.**—Generally the angle varied from 4° to 6°, according to the size of the lamp and the length of the screen. In some cases it varied from 1¼° to 10°.

Reports by individual surveyors:—

*Mr. Jackson and Mr. Marshall.*—Seventeen ships inspected; mean angle 4° 42′.

*Mr. Munro.*—Angle would range from 4° to 4° 45′.

*Mr. Colvill.*—Usual angle 4⅓° to 5¼°, according to the length of the screen and the relative positions of the outer edge of the wick and the inboard edge of the lens.

*Mr. Shrigley, Mr. Wotherspoon, and Mr. Hutchison.*—Angle was greater than that required by the new regulations. It was about 5° or 6°.

*Mr. Carver.*—The angle was practically the same as that required by the present rule.

*Mr. Smith.*—The lights were not formerly screened to more than 4°.

**Hull District.**—Of 371 ships which were inspected—

52·29 per cent. were screened to a larger angle than 4°.

26·95 per cent. were screened to 4°.

20·75 per cent. were screened to less than 4°.

that is to say, more than 79 per cent. were screened to 4° or over.

**London District.**—The majority of vessels were screened to 4° or over. The old instruction was a rule of thumb, and the result was dependent upon the position of the wick. In practice it was found to indicate an angle of about 4°.

From a return handed in by the Marine Superintendent of the Peninsular and Oriental Company, it appears that in 80 per cent. of their vessels the lights were screened to 4° or over.

**Plymouth District.**—Reports by surveyors:—

*Mr. Sparrow, Mr. Mackinlay, and Mr. Holman.*—In most cases the angle was about 4°; in a few cases a little less.

**Cardiff District.**—In the great majority of cases the angle was diminished when the lights were re-screened. It appears that only about 12 or 13 per cent. of the vessels inspected were screened to less than 4°. In the remaining 87 or 88 per cent. the angle varied from 4° to 6°; in some instances it was as much as 8° or 9°.

From a statement handed in by one of the masters of the Lambton fleet of colliers, it appears that in every one of their 27 vessels, the angle of screening was reduced.

**Liverpool District.**—Of 369 vessels inspected—

115 or 31·2 per cent. were over 4°.

90 or 24·4 per cent. were at 4°.

161 or 43·6 per cent. were under 4°.

In three cases the lights diverged.

*Result.*—More than 55 per cent. were screened to 4° or over.

**Glasgow District.**—No record kept.

In almost every case some slight alteration was required; sometimes the angle was increased, sometimes diminished. In several instances the angle was greater than 4°, and in some it was as much as 8°.

| 70 | 174·79 | 122·23 | 104·79 | 52·23 | 70 | 69·38 | 17·37 | Collision. | Do. |

The reason of the results marked negative is owing to the bearing being given from the intersection of the side lights, and consequently the bearing is that of the outer edge of the side light, and is not the bearing of the ship, and in these cases the distance to the intersection is greater than the distance between the two ships. It has been argued that no regulation is necessary for the information and guidance of shipmasters when ships are approaching one another in this manner; the same argument would equally apply to all other cases. Mr. Gray's verses, "Green to green, red to red, perfect safety, go ahead," would not apply unless the lights were screened in the manner contemplated by himself. In the cases shown above, they would mean either dangerous proximity or collision.*

D. M., 1893.

---

## No. 5.—REPORT on the 1891 EXPERIMENTS by Sir D. MURRAY and Mr. SAMSON.

### *Memorandum by Sir D. Murray.*

On M. 7273–91, I obtained permission to expend 25*l.* in experiments on ships' side lights to determine:—

(1.) The angle at which it was desirable the most convergent rays of the two side lights should cross ahead of the ship.

(2.) In what manner the lights should be fitted so as to ensure their rays not being lost in the water in the immediate vicinity of the ship when the ship is listed to a considerable angle of heel.

The first experiment was tried at the Glengall Iron Works with a pair of full-sized side lights having plano-convex lenses.

The result was so unsatisfactory that I determined to stop the experiments until I could obtain a pair of lights which should be tested at Shoeburyness both for distance and depression.

I therefore obtained authority from the Board to order a pair of standard lights.

I communicated with Messrs. Harvie, of Glasgow, and ordered a pair of side lights from them subject to their fulfilling the following conditions: (1) that they should have a vertical divergence above and below the horizontal plane of 20°; (2) that, with this vertical divergence, they should show, when horizontal, the distance required by the instructions.

* *See* Plate VI.

All the mechanical arrangements for these experiments have been fitted under the superintendence of Mr. Samson, including the screening of the lights and the subsequent sighting of the screens; this has been done with the utmost care, and the following joint report of Mr. Samson and myself of the three nights trials will, by the aid of diagrams, explain clearly how this has been accomplished.

(Signed) D. MURRAY.

### *Report of Sir D. Murray and Mr. Samson.*

The two principal points on which we have to report to the Board of Trade are contained in the resolutions adopted by the Washington International Conference, viz.:—

(1.) General Division, 1–5. "The lantern should be "so constructed as to ensure the light having at "least the required minimum power in the ideal "line connecting the lantern with the horizon, even "though the vessel be heeled one way or the other "10 degrees."

(2.) General Division, 1–8. "The side lights should "be so screened as to prevent the most convergent "rays of the light being seen across the bows more "than half a point."

We will now give a detailed account of the experiments, and then make our recommendations as to what we think the Board's instructions should be to their surveyors with reference to the practice of the mercantile marine of this country.

In conducting the experiments, and in making up our minds as to the angle to which the side lights should be screened, it was necessary to determine exactly what it was that we wished to attain.

This was determined as follows: That at 200 yards forward of the intersection of the most convergent rays of the lights at the middle line the two side lights should be plainly visible to a ship approaching end on, and should practically present the same appearance to an observer, whether standing in the middle or on either side of the bridge or deck, no matter what the beam of the approaching ship might be.

The point at which the most convergent rays of the two lights will apparently cross the middle line will not agree with the theoretical distance, as both lights will apparently cross nearer than the theoretical crossing-point, the red nearer than the green; but, for all practical purposes, the theoretical crossing-point, due to the angle at which the lights are screened, may be adopted.

*of each others sidelights, than when they are*

from both sides of the bridge of the approaching ships and a very slight reduction in the bearing between the two ships would make the red light invisible.

If the lights are screened to an angle of 1° two steamships steering parallel courses and bearing from the intersection of one anothers sidelights any angle exceeding 1° on each other's starboard bow, will see each other's green lights only.

If screened to 2° on all bearings greater than 2° they will see one another's green lights only.

If screened to 3° on all bearings greater than 3° they will see one another's green lights only.

To practically test this, experiments should be carried out in such conditions of the atmosphere as would enable an observer to see the sidelights at no greater distances than are here referred to.

Former experiments tend to show that reflected light would not be visible at these distances.

*Remarks on the Experiments at the Glengall Iron Works.*

The lights were extremely faint long before they became for all practical purposes invisible, and they did not show plainly, and the green light not at all, even at the theoretical distance from the middle line due to the angle at which they were screened. Columns 7 and 8.

These experiments show that if a ship of from 30 to 60 ft. beam was directly approaching these lights at a distance of 600 ft. from their intersection, or 885 ft. from the lights, they would present a different appearance to observers stationed on the starboard side, in the middle, and on the port side of the bridge.

That the experiments were not made at the exact distance of 600 ft. from the intersection of the rays of the two lights was owing to the space at our disposal at the Glengall Iron Works being insufficient.

We have every reason to believe that lights are screened to as small an angle as 3°, indeed we have a diagram sent by one maker showing the lights screened to a still smaller angle.

It may possibly answer in some cases, but we are of opinion that so small an angle is undesirable, and as a general instruction would be unsafe.

In the foregoing experiments the screens were sighted by a small lantern hung alternately 15 ft. on each side of the middle line at a distance of about 680 ft. from the side lights.

*Trial of a pair of Side lights having dioptric lenses (and stated by the makers, Messrs. Harvie, to have a vertical divergence* of 20°) when screened to an angle of 4° and placed 30 ft. apart.*

At 1,200 ft. from the lights, or 985 ft. from the theoretical point of intersection of the most convergent rays of the two lights forward of the ship, the red light became so faint as to be practically invisible at 110 ft. 6 ins. to the left of the middle line when facing the lamps. Green became practically invisible at 66 ft. 5 ins. to the right of the middle line.

At 815 ft. from the lights, or 600 ft. from the theoretical point of intersection of the most convergent rays of the two lights, the red light became practically invisible at 104 ft. 5 ins. to the left of the middle line. The green light became practically invisible at 73 ft. 7 ins. to the right of the middle line.

These experiments appeared to differ so materially from those obtained at the Glengall Iron Works, that it was thought desirable to try another pair of lights, and a pair of full-sized lights, having dioptric lenses, were selected from those in stock at Shoeburyness, and the screens were altered to fit them.

When screened to an angle of 4° they gave the following results:—

At 1,200 ft., 985 ft. from their intersection, the red light became practically invisible at 134 ft. 3 ins. to the left of the middle line. The green light became practically invisible at 42 ft. 3 ins. to the right of the middle line.

At 815 ft. from the lights, or 600 ft. from their intersection, red became practically invisible at 98 ft. 9 ins. to the left of the middle line. Green became practically invisible at 43 ft. 9 ins. to the right of the middle line.

These distances were carefully noted by three observers, although it is obvious that either varying conditions of the atmosphere, or the difficulty of determining the exact point at which a light becomes practically invisible, have affected the results, and probably if the same experiments were tried on some other night, the distances, owing to atmospheric and other causes, would be found to differ somewhat from the present ones.

It is also clear that the character of the green light will in all cases greatly affect the result.

*Trial of Messrs. Harvie's Lights for Distance and Depression.*

The night was not particularly favourable to the lights, for although apparently clear, light mist was occasionally swept across between the observers and the lamps, as indicated by their varying brilliancy.

At a distance of two statute miles both lights were visible, but the green was faint.

At 4,002 yards, red was plainly visible to the naked eye; green was barely visible, but plainly seen through binoculars.

On moving 286 yards to the left of the middle line, *i.e.*, when looking towards the lights, red became invisible, the green being fairly visible.

On moving 225 yards to the right, green became practically invisible, the red being plainly visible.

Depression.

The green light at 0° broadside on to the observer was very distinct.

The green light was depressed to 20°, the observers remaining at the same distance, viz., 4,002 yards.

At this angle and distance, it was invisible even when looked for with binoculars.

* The divergence was tested by the makers by a ground glass screen in a darkened room.

When depressed to an angle of 15°, it became visible to the naked eye to two out of three of the observers.

At a distance of two statute miles, the green was visible to the naked eye at 15°, and through binoculars when depressed to 18°.

At 1½ statute miles, the green light was just visible to the naked eye when depressed to 18°, and plainly at 15°.

At 2,100 yards, the green was just visible to the naked eye, when depressed to an angle of 20°.

The green light was placed on the end of a movable arm, so fitted as to keep the light, when depressed to an angle of 20°, 5 ft. above the sand, or about the height of an observer's eye, when seated in the artillery waggon. It was also broadside on to the observers.

We consider the foregoing results are very satisfactory. At the time of the former experiments at Shoeburyness in April 1880, it was thought useless to test the side lights for elevation and depression at a greater distance than 1,000 yards; these experiments show a marked progress.

It was not practicable to carry out any further observations in the time at our disposal, which was limited by the tide, but experiments previously carried out at Shoeburyness show that the angles selected were the most crucial ones, and we think they are sufficient for our purposes.

*Recommendations.*

(1.) General Division 1–5 of the resolutions of the Washington International Conference:—

"The lantern should be so constructed as to ensure the light having at least the required minimum power in the ideal line connecting the lantern with the horizon, even though the vessel be heeled one way or the other 10°."

Many merchant steamships, when their coal is nearly consumed, especially when grain-laden, list as much as 20°, and some very narrow ships have been known to reach the Mersey with as great a list as 23°.

We are, therefore, of opinion that the side-lights should either be so constructed as to have a vertical divergence both above and below the horizontal plane of 20°, in which case the least powerful of the two lights—the green—when depressed to an angle of 20° should be visible to the naked eye at a distance of one sea mile, or else the lights should be hung in gimbals. *See* Diagrams and explanations at the end of our Report.

(2.) General Division 1–8 of the resolutions of the Washington International Conference:—

"The side lights should be so screened as to prevent the most convergent rays of the light being seen across the bows more than half a point."

In carrying out experiments to determine the angle at which the lights should be screened, it was most difficult to distinguish between the true rays of the light and the reflected rays. It is obvious that the true rays, as distinguished from the reflected rays, cannot be seen at a greater distance from any point of the middle line than that which is due to the angle at which the light is screened, and the theoretical distance is probably for all practical purposes correct so far as the red light is concerned, though the light will appear bright to a greater distance, and the reflection at a distance of 600 ft. from the theoretical intersection of the rays of the two lights will be visible to considerably more than twice that distance.

With the green light this does not appear to be the case. The light and its reflection are much fainter than is the case with the red, and its rays are not visible so near to the ship as the red.

We are of opinion that the lights should not be screened to a smaller angle than 4° each, and even then great care will have to be taken to ensure the quality of the green light.

To try the distance at which this light can be seen on the opposite side of the middle line at a distance of 600 ft. from the intersection of the lights will probably afford the makers quite as much information as to the quality of the light as the long-distance test would.

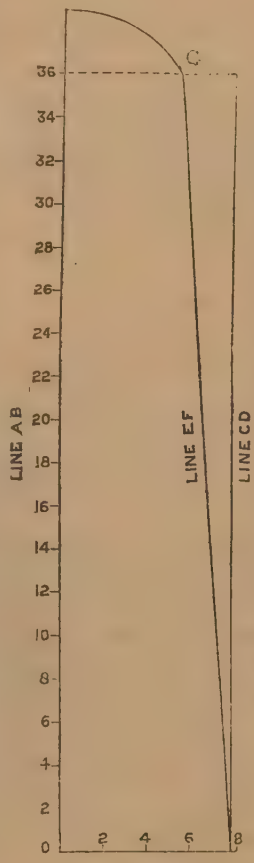
It would not be necessary for them to test every pair of lamps, but only one pair of each pattern they manufacture, provided always that the colour and quality of the glass was the same.

As it is important that all lights carried by vessels belonging to the Mercantile Marine of this country should be screened in exactly the same manner, especially having regard to uniformity of practice on the part of the Board's surveyors, we attach diagrams and explanations showing clearly how this is to be done, and if this Report is approved of, they will be embodied in the instructions.

*Instructions as to the manner in which the Side lights of Merchant Ships and Steamships are to be screened.*

They are always to be fitted as follows, excepting when in turrets, in which case it may be thought desirable so to arrange the screens as to dispense with chocks:—

Scale, ¼ inch = 2 inches.



Line AB represents the outer surface of screen which is always to be 36 inches in length forward of a line passing transversely through the outer edge of wick. It must be in a line parallel to the keel.

Line CD is a line drawn parallel to AB at a distance equal to the distance between the outer edge of the screen and the outer edge of the wick.

Line EF is a line projected from the outer edge of the wick at an angle of 4°, measured from a line, CD, parallel to the vessel's keel.

Its distance at G from the line CD will always be 2·5 inches.*

Its distance at G from the line AB will always be equal to the required depth of the chock.

The diagram represents the starboard lamp.

(Signed) D. MURRAY.
P. SAMSON.

*List of Diagrams attached to the Report.*

1. Diagram showing the distance from the lights (when screened to an angle of 4°) at which their most convergent rays cross the middle line forward of the lights, varying with the distance between the outside of the wicks on one side of the ship to the outside of the wicks on the other side of the ship. (*See* Plate IV.)

2. Diagrams showing how Messrs. Harvie's lights were screened at the trials at Shoeburyness.

3. Diagram and explanations as to the hanging of side lights in gimbals, and also of fitting them so that the screens may adapt themselves to the heel of the ship. (*See* Plate V.)

4. Diagram showing the screening of side lights to an angle of 4° when hung in the ordinary position. (*See* Plate III.)

5. Diagram showing how lights may be screened in turrets to an angle of 4°. (*See* Plate II.)

* 2·5 inches would appear to be exact enough for all practical purposes, but if carried to another place of decimals it would be 2·52.

## Result of previous Experiments with Side Lights at Shoeburyness to determine their Visibility at different Degrees of Elevation and Depression.

### Result of Trial of Ships' Side Lights at Short Ranges in Marsh in presence of Representatives of Board of Trade and Admiralty.

## No. 6.—Report by the Assistant Superintendent of Experiments on the 1891 Experiments.

### Experiments with Ships' Lights for Board of Trade.

Trial of Ships' Side Lights—Harvie's of Glasgow—*vide* Board of Trade Letter dated 19th May 1891, M. 10364.

Table of Results of Experiments at various Angles of Heel—Green Light showing 8 points, and long distance Tests of both Lights right ahead.

| Place. | Date. | Description of Lamps. | Port or Starboard. | Oil used. | Time when Lighted. | Distance of Lamp to Observer. | Angle of Heel. | Position of Lamps. | Distance from Centre Line at which Light became invisible. | Appearance to Observers Ahead. | Remarks. |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Shoeburyness. | 25 June 1891 | Harvie's Side Lights. | Port - - | Mineral oil | 1 hour before experiment. | 1,900 yards | — | — | — | Just visible - | Weather very misty. None light barely visible from lamp station. Sheerness lights not visible. Long distance tests postponed till following night, owing to mist. |
| | " | | Starboard - | " | " | 1,900 yards | — | — | — | Just visible - - | |
| | 26 June 1891 | " | Port - - | " | " | 4,000 yards | 0 | In screens 30′ apart screened to an angle of 4°. | — | Visible with difficulty. Both easily with binoculars. | Slightly misty. None light fairly visible. No Sheerness lights visible. No lights in Channel. As the port light decreases in visibility, the starboard light increases, and *vice versâ*. |

For Superintendent of Experiments.

No. 7.—MEMORANDUM by Sir DIGBY MURRAY, Bart., on the REGULATIONS as to SIDE LIGHTS. (Departmental Paper No. 179.)

Regulations as to side lights from 1862 to the present time.

The schedule to the Merchant Shipping Amendment Act, 1862, Table (*c*) requires as follows:—

Art. 3 (*b.*) On the starboard side, a green light so constructed as to show an uniform and unbroken light over an arc of the horizon of 10 points of the compass, so fixed as to throw the light from right ahead to two points abaft the beam on the starboard side, and of such a character as to be visible on a dark night with a clear atmosphere at a distance of at least two miles:

(*c.*) On the port side, a red light so constructed as to show an uniform and unbroken light over an arc of the horizon of 10 points of the compass, so fixed as to throw the light from right ahead to two points abaft the beam on the port side, and of such a character as to be visible on a dark night with a clear atmosphere at a distance of at least two miles:

(*d.*) The said green and red side-lights shall be fitted with inboard screens, projecting at least three feet forward from the light, so as to prevent these lights from being seen across the bow.

These three sub-articles have not been altered, and are still in force, but in the proposed Regulations, as agreed to at Washington and approved by the Rule of the Road Committee in London, they have been very slightly varied.

Interpretation of the foregoing sub-articles:—(*b*) and (*c*) mean that the full volume of light is to be seen from right ahead to two points abaft the beam of the ship, otherwise it is clear it would not show *an uniform* light over an arc of the horizon of 10 points of the compass.

(*d.*) Eminent counsel have pointed out that being seen across the bow means across the bow of the ship, *i.e.*, anywhere abaft the stem. I must confess that this was not my original reading of the sub-article, which I have always until recently considered to have been drafted in error; but how eminently reasonable the contention of counsel is, a little reflection will I think show. If this sub-section means that the lights shall not be seen across the path of the ship, then this sub-article is directly in contravention of sub-articles (*b*) and (*c*), Art. 3, as well as of Art. 15, to which latter the late Mr. Thomas Gray's verses apply: "When all three lights "I see ahead, I port my helm and show my red." And besides this it must be remembered that in 1862 the majority of side lights were carried well forward, and a 3-foot screen would, in most cases, prevent the lights being seen across the ship anywhere abaft the stem; but it would be an absurd enactment if it was intended to prevent the rays crossing the path of the ship; that, without a chock, would require a screen of enormous length, and a great depth of chock is very undesirable.

In the following observations I propose to consider what has been done by the Board of Trade to carry out the Regulations as regards side lights from 1868 up to the present time.

The present objections of shipowners and others appear to me to apply rather to the International Regulations than to the Board of Trade Instructions for carrying them into effect, or in other words, they place such an interpretation upon the International Regulations as would, in my opinion, require their entire revision.

There always will be a difference of opinion as to the manner in which Art. 3 ought to be drafted, whether the lights ought to be screened in a line parallel with the ship's keel, or whether they should be so screened as to cross at some angle ahead of the ship, and if so, at what angle; but it is foreign to my present purpose to do more than discuss how the Board of Trade have, in the past, and also in the present, endeavoured to carry the International Regulations in this respect into effect.

In 1868 and 1872 the Board of Trade advised their surveyors as follows:—"If the red and green rays cross "each other immediately on passing the stem, the red "light will be seen on the starboard bow, and the "green light on the port bow, as shown in figure 8; "but on the other hand, if they do not cross, at least "to a slight extent, they cannot both be seen ahead."

Woodcuts were attached showing chocks, &c. fitted to a 3-ft. screen, the depth of the chock being equal to the distance from the inner edge of the lens to the outboard edge of the screen, the angle from the middle of the wick to the outer edge of the chock being 3°.

In 1875 a printer's error occurred in the Instructions, which is abundantly shown both by the woodcuts and also by a previous passage in the same Instructions.

The paragraph in question runs as follows:—

For both lights to be seen ahead it is necessary that the red and green rays should cross at a certain distance ahead. Surveyors will probably find that if the inboard edge of the *wick** touch a line that is parallel with the keel of the ship, and that cuts the outer edge of the forward end of the inboard screen, the rays will cross suitably.

In 1887 and 1891. A line drawn parallel to the keel from the inner edge of the lens indicates the depth of the chock, and this line is there referred to as the line of reference, as illustrated by the accompanying woodcut.

The following is a statement of Captain Wilson as to the angle to which lights were screened prior to 1892, and this has been abundantly confirmed by separate and

* Wick should be lens.

Captain R.A.

independent statements made by the Board of Trade staff in different parts of the country.

"In the case of the majority of vessels surveyed in the London district the side lights were found to be screened to an angle of 4° or over.

"In the instruction prior to the present one of 1892, it was suggested to surveyors with reference to the drawings contained therein, showing screens 3 ft. in length, that the distance from the inner edge of the lens to the outer edge of the screen showed the required depth of the chock, and although this was a rule of thumb which was more or less dependent upon the position of the wick, we found in practice that it indicated an angle of about 4°, which the present instructions more accurately and definitely define.

(Signed) C. P. Wilson."

Excepting that shipowners accuse the Board of Trade of making sudden and radical alterations in the screening of side lights, I do not think there is much interest in discussing past history. The real question is, whether the Board of Trade Instructions adequately and properly carry out the Regulations for Preventing Collisions at Sea, and if not, how they can be best amended. I am of opinion that they do, for reasons I will state further on. A writer recently attacking the Board of Trade on this question points out that the Washington Conference made a blunder as to the angle to which side lights were previously screened by the Board of Trade, which he believes he was the first to discover. This was not the case; it was noted the moment the protocols from Washington reached this department, and I pointed out to Sir George Nares that the angle had been over-estimated, but I do not think this error in the least affects the Board of Trade. The same writer points out that as the lights were previously screened to 3°, they have subsequently been increased to 4°. This is not the case; the angle of 3° was measured from the centre of the wick, that of 4° from the outer edge of the wick, practically the same thing.

Now let me discuss the question of screening on its merits. The International Regulations require that an uniform light, *i.e.*, the full volume of light, shall be seen ahead of the ship. Let us consider what angle of screening is necessary to insure this, 1°, 2°, 3°, or 4°. I think it unnecessary to discuss angles exceeding 4°.

I attach a table showing the distance ahead of the ship at which the full volume of the lights will cross the middle line, and also the distance at which the full volume of light would be visible to an observer on either side of a bridge 50 feet in width; and we now have vessels in the Mercantile Marine having a beam considerably in excess of 60 feet.

It would not do to limit the position of the observer to the bare 50 feet, and I have added 5 feet to the half breadth for this purpose. And this is certainly not more than is necessary, especially as regards the green light, as the actual distance of visibility from the middle line will always be less than the theoretical distance.

One inch is the smallest width of wick allowed by the Board of Trade Instructions, and the width varies from this to one and three-quarters, and over, in the case of colza oil. The table shows the distances for wicks, one inch and one and a quarter inch in width. I think a reference to this table will show at once that screening the side lights to an angle of either one or two degrees would not be a reasonable compliance with the Regulations for Preventing Collisions at Sea, and that if it was considered desirable to screen the lights to so fine an angle, it would probably be considered necessary to alter the International Regulations.

In rainy and partially foggy weather it is of the utmost importance that the whole light, and not a mere edge of light, should show ahead of the ship.

With reference to the angle of 3° two full-sized lamps were tested by Mr. Samson and myself, at the Glengall Iron Works, with the result that when screened to an angle of 3° we found at a distance of 2·4 ft. from the lamps the green light became invisible at a distance of 17 ft. from the middle line instead of 29 ft., the theoretical distance; and Mr. Samson and I were entirely convinced, after experimenting at short and long ranges at Shoeburyness, with lamps burning two-and-a-half times the usual quantity of oil, that the green light could not be depended upon to show the theoretical distance from the middle line, and we therefore very reluctantly came to the conclusion that 3°, which judging simply from investigation on paper we had previously to experiment considered would probably be the proper angle, was insufficient, and we adopted what appeared to us to be the only alternative and recommended 4°.

That this 4°, coincided with previous practice was purely an accident, *i.e.*, in arriving at this decision we neither of us considered what had been the previous practice of the Board, but merely what angle appeared to us to be the most desirable.

The reason for recommending one angle for all ships, irrespective of their beam, was to ensure that at distances, say, from quarter of a mile to 2 miles, the distance between the red and green rays should be practically the same for all ships, which would not be the case if the lights were merely screened with a view to their crossing at some definite distance ahead of the ship

I trust I have been able to show that the Board of Trade Instructions for carrying into effect Article 3 of the Regulations have been reasonable and proper instructions from 1868, five years before I joined the Board of Trade, up to the present time, and if the Board of Trade ask now for a more definite angle of screening it is—

(1) because greater uniformity has been proved to be necessary;

(2) because an alteration has taken place in the manufacture of side lights, and the positions of the wicks with reference to the lanthorn vary more than they used to do, and consequently render more precise instructions imperative.

I attach lists of vessels the screening of which have been reported to the Board of Trade by their surveyors, and the striking want of uniformity therein shown amply justifies to my mind the Board's recent action. These lists show that the contention of the Thames pilots was urged in ignorance of previous practice; but even if it were not, the regulations are regulations for preventing collisions at sea, and are not regulations for preventing collisions in rivers or inland waters.

I am inclined to think the grievance of the pilots is a sentimental one, but, if it is not, it is a question for the local authorities, and is one which, in my opinion, can be very easily provided against.

The list of vessels of which the angle to which the side lights have been screened has been noted is constantly increasing, but those already printed appear to be a very fair sample of existing practice.

Since writing this, the report of Captain Wilson, Mr. Samson, and Mr. Richards has been received as to the experiments at Westminster, in which they state that when the side lights were screened to an angle of 4° they were found to be screened in exact conformity with the Board of Trade's old Instructions.

(Signed) D. Murray.

| Linwood | 4 | 4 | |
| Nettie Murphy | 6 | 4 | Port light now screened to 4°. |
| North Devon | 1 | 2 | Now screened to 4°. |
| Newman Hall | 4 | 4 | |
| Phyllis | 6 | 5 | Now screened to 4°. |
| Quickstep | — | — | Lights partially obscured. Now screened on upper bridge to 4°. |

| Name of Vessel. | Port Light. | Starboard Light. | Remarks. |
|---|---|---|---|
| | Degrees. | Degrees. | |
| Rowtor - - - | 4 | 4 | |
| Strathspey - - | 8 | 4 | |
| Trevaynor - - - | — | — | Lights partially obscured in towers. Towers condemned, and lights now screened on upper bridge to 4°. |
| Tockwith - - | 4 | 4 | |
| Wm. Symington - | Screen out | 2 | Port light now screened to 4°. |
| Widdrington - - | 2 | 2 | Lights partially obscured. Screens now put 1′ further out, and lights screened to 4°. |

*Abstract.*

14 vessels' lights screened to no rule.
4 vessels' lights screened to finer angle than 4°.
3 vessels' lights screened to greater angle than 4°.
10 vessels' lights screened to angle of 4°.

31

No. 8.—Supplementary List of Vessels inspected in the London District.

| Name and Official Number. | Owners. | Angle to which Lights were found to be Screened when first visited. | Remarks. |
|---|---|---|---|
| Argonaut; 72,412 - | T. Carmichael, Greenock | Port $\frac{1}{2}$°, starboard 0° - - | Starboard outer edge of lamp wick in line with outer edge of chock. |
| Miltiades; 60,710 - | W. Henderson, Aberdeen | Port 6°, starboard 5° - - | |
| Lady Elizabeth; 81,576 - | G. Karran, Isle of Man - | Port 4°, starboard 4$\frac{1}{4}$° - - | |
| Salamis; 70,443 - - | W. Henderson, Aberdeen | Port 6°, starboard 6$\frac{1}{2}$° - - | Lanthorns could be moved several degrees either way. |
| Mermerus; 67,904 - | Thos. Carmichael, Greenock. | Port 6$\frac{1}{4}$°, starboard 7° - | |
| Aristides; 70,454 . - | W. Henderson, Aberdeen | Port 5°, starboard 4° - - | |
| Norman Macleod; 72,420 | J. G. Nicholson, Liverpool. | Port 4$\frac{1}{2}$°, starboard 5$\frac{1}{2}$° - - | Lanthorns could be moved in cage. |
| Orontes; 77,465 - - | W. Henderson, Aberdeen | Port 4$\frac{3}{4}$°, starboard 7° - - | Both these lights were screened by the catheads to 1° or nearly so. |
| Karoo; 85,449 - | C. R. Burgess, Wolfville, King's Co., N.S. | 5° across the bow - - | These screens were fitted below the mainrail, the lights being secured in boxes. These have been removed, and the screens are now fitted on stanchions secured to rail by an iron stay, and screened to an angle of 4°. |
| Elisabeth Mentz; foreign | - - - - | It was not possible to ascertain the angle in this case, as the screens were old and broken, and the single stanchions which supported them were much bent. | The lights were carried aft on each quarter, but have now been placed at the fore side of fore rigging, and screened to an angle of 4°. |
| Rhone; 72,547 - - | James Nourse, 3, Fenchurch Street, City. | These lights were carried above forecastle deck and abreast the forecastle breast beam, and were found to be about $\frac{1}{4}$° within the 4° required = 3$\frac{3}{4}$°. | No alteration was made in this case. |
| Caledonia; 76,579 - | Jas. Duncan, 79, Mark Lane, City. | These lights were carried amidships, and were found to be screened to 4°. | The master afterwards stated that the screens were altered at Queenstown by the Board's surveyor. |
| Bazalgette; 94,298 - | The London County Council, Spring Gardens, London. | These lights were carried amidships on ends of flying bridge, and were found to be screened to 3°. | These lights had apparently at one time been screened to 4°, as a batten $\frac{1}{2}$ inch thick had been nailed on to the chock, and by removing this batten it gave the required angle of 4°. |
| Violet; steam yacht - | Not known. Agents, Cox and King, 5, Suffolk Street, Pall Mall. | The lights were carried on stanchions at fore part of mainwaist. The starboard light was found to be screened 7$\frac{1}{2}$° across bow, and the port light 5° across bow. | The screens have been set in a fore and aft line, and screened to 4°. |
| Accomac; 86,294 - | Tapscott S.S. Co., Ld., 39, Old Hall Street, Liverpool. | These lights were carried on the fore end of bridge deck, and the port light was found to be screened 5$\frac{1}{2}$° across the bow, and the starboard light 3° across the bow. | The screens have been set to an angle of 4°. |
| Douglas; 14,852 - - | N. Bate, Sea View, Aberavon, Glamorgan. | These lights were carried at after part of mainwaist, and were found to be screened to an angle of 6°. Both lights showing into the fore rigging. | The screens have been shifted from after part of mainwaist to fore side of fore rigging, and are now screened to angle of 4°. |
| Opal; steam yacht - | Not known. Agents, Cox and King, 5, Suffolk Street, Pall Mall. | These lights are carried on ends of flying bridge, and were found to be screened to an angle of 10° across the bow. | These lights have now been screened to the required angle of 4°. |

APP. 2, No. 8.

| Name and Official Number. | Owners. | Angle to which Lights were found to be Screened when first visited. | Remarks. |
|---|---|---|---|
| Romanoff; 70,436 - | J. B. Nicol, Aberdeen - | These lights are carried on after end forecastle deck, and were found to be screened to an angle of 3° across the bow. | These lights have now been screened to an angle of 4°. |
| Duke of Argyll; 52,816 - | H. E. Montgomerie, Managing Owner, 36, Gracechurch Street. | These lights are carried at after end of forecastle deck, and were found to be screened to an angle of 9° across the bow. | The centre of the light when projected forward, was found to strike the cathead, on the lower edge 2 feet 6 inches out from the ship's side. The catheads thus obscured the lights on each side. The screens have now been raised 12 inches, this being found to be sufficiently high to allow the lights to be seen above the catheads. They have now been screened to an angle of 4°. |
| Merchant; 58,029 - | Messrs. Bull & Co., Newhaven. | Port 0°, starboard 2°, across bow | Screens carried on overhanging stanchions aft, chocks removed and boards cut off 3 feet forward of light. (Inclination of screens to keel giving required angle.) |
| S.S. Viking; 63,851 - | The London, Brighton, and South Coast Railway Company, Newhaven. | Port 2°, starboard 5°, across bow | Starboard stanchions adjusted and boards cut off 3 feet forward of light. |
| Sch. Robert Brown; 69,771 | David Marrow, Connah's Quay, Flint. | Starboard 6°, port 7°, across bow | Defect caused by stanchions being very much bent. |
| George B. Balfour; 83,999 | John Fisher, Fisher Building, Barrow. | Starboard 4°, port 4°, across bow | Screens carried on overhanging stanchions in mizzen rigging. |
| Rennes S.S.; 54,597 - | London, Brighton, and South Coast Railway Company, Newhaven. | Starboard 2°, port 2°, across bow | Screens outside bridge 4 feet forward of light; chocks reduced to give 4°. |
| Sch. Aeron Lass; 9,830 - | J. Jones - - | Port 8°, starboard 6°, across bow | Stanchions very much bent and deck's sockets worn, causing stanchions to play considerably. |
| Sussex Maid; 11,064 - | Mr. Robinson, Newhaven | Port 6°, starboard 6°, across bow | Stanchions at fore rigging; lamps recessed; and 2-inch chocks fitted 3 feet forward of lamps. |
| Pennine; 56,480 - | Messrs. Bull & Co., Newhaven. | Starboard 4°, port 6°, across bow | Stanchions are slight and easily bent. (Owner intends replacing by stronger ones.) |
| Mindet S.; foreign - | Agents, Messrs. Andorsen, Becker, & Co., 4, Eastcheap. | Port 6°, starboard 6°, across bow | Screens fitted on bulwarks forward of fore channels, 2½-inch chocks added to give required angle. |
| Bn. Zulu; 65,677 - | John Grace, Guernsey - | Port 6°, starboard 4°, across bow | Defect due to stanchion being bent, but this was set back in my presence. |
| Crescent (Tug); not regd. | - - - - | Port 6°, starboard 6°, across bow | Chocks on fore end of screen boards increased to 3½ inches. |
| S.S. Idlewild; 68,873 - | Metropolitan S.S. Co., 27, Leadenhall Street. | Port 4°, starboard 4°, across bow | Screen boards 3 feet with 3 inch chocks, carried on overhanging stanchions secured to bridge rail. |
| S.S. River Derwent; 85,930. | S.S. River Derwent, Ltd., 69, Buchanan Street, Glasgow. | Port 4°, starboard 4°, across bow | Screens secured to ends of bridge in line with keel; screens 3 feet 9 inches forward of light. Lamps recessed to give required angle. |
| City of Glasgow; 56,172 - | Geo. Smith, 45, West Nile Street, Glasgow. | Port 5°, starboard 4°, across bow | Chock to port screen increased by ¾ inch to give required angle. |
| George (Ketch); 13,623 - | R. A. Smith, Chichester - | Port 8°, starboard 6°, across bow | Port stanchion straightened and chocks on both boards increased by 1¼ inches. |
| S.S. Montanes; foreign - | Messrs. McAndrew & Co., Cannon Street. | Port 4°, starboard 4°, across bow | Screens secured outside of bridge. |
| S.S. Peeress; 90,333 - | Messrs. Taylor and Sanderson. | Angle could not be checked, as lamps were damaged, badly fitted, and burners required adjusting to centre of lens. | Screens fitted on overhanging stanchions outside bridge. Report sent to surveyors at Blyth. |
| Formosa; 93,427 - - | P. and O. Company - | 5° - - - | Side lights carried on upper bridge. |
| Rome; 81,820 - - | P. and O. Company - | Right ahead - - - | Side lights prior to alterations were carried on lower bridge. The rays were obscured by a high topgallant forecastle and permanent fittings on forecastle. The side lights are now fitted to upper bridge. |
| Paris; 95,854 - - - | London, Brighton, and South Coast Railway Company. | 3° - - - | Side lights carried on paddle boxes. |
| Yorkshire; 96,366 - | Bibby Steam Ship Company, Limited. | 1¾° - - - - | Side lights carried on bridge. |
| Patriarch; 60,696 - | W. Henderson, Aberdeen | Port 6½°, starboard 5½° - - | Fitted at after end of top gallant forecastle. |
| Gladova; 93,820 - - | G. Wakeham, Liverpool | Port 5¾°, starboard 5° - - | Fitted in towers. |
| Camana; 29,935 - - | J. Burgess, Swansea - | Port 4°, starboard 2¾° - - | Port screen is moveable to the extent of 3° or 4°. Starboard screen is bent inboard nearly 15° from upright, and rigid in this position. |

The above patterns represent a great number of lights. Messrs. Ridsdale, for instance, say they have manufactured 4,800 lamps of the pattern marked*; and it is to be noticed that during the last six months, although the pattern of the lanthorn in this case has not been changed, the wick has been moved one inch nearer the side of the lamp, so as to enable the present Board of Trade rule to be carried into effect, *i.e.*, so that the centre of curvature of both lens and reflector may be the centre of the wick.

No. 10.—LETTER from the GERMAN LLOYD to the BOARD OF TRADE.

52, Markgrafenstrasse Berlin, W.,
February 14th, 1895.

SIR,

REFERRING to the recent discussions on the screening of side lights on board of ships, we herewith beg to enclose for your information a copy of a report delivered by us, under date of January 24th last, on this subject, to the See-Berufs-genossenschaft in Germany.

Trusting that the statements therein will be of some interest to you, we remain,

Yours obediently,
GERMANISCHER LLOYD.
(Signed) ULRICH. MIDDENDORF.

The Assistant Secretary,
Marine Department, Board of Trade.

(Translation.) Enclosure.

REPORT by the GERMAN LLOYD on the FIXING and SCREENING of the SIDE LIGHTS of SEA-GOING VESSELS.

I.—THE FIXING of SIDE LIGHTS.

We do not think that it is desirable that definite instructions as to the method of fixing the side lights should be issued by the Marine Association. The master is the person who can best decide where the lights must be placed in order to be properly protected from the sea, and not obscured by sails, boats, davits, tackle, or by persons standing in front of them; he will be able to judge in exceptional circumstances whether the lights require to be moved in order that they may be properly secured, and show in the manner prescribed by the regulations, &c. The master should therefore, be left responsible for the proper method of fixing the lanterns, and the only step taken should be to insert in the Collision Regulations some general directions similar to those issued by the English Board of Trade (*see* p. 4 of the "Journal of Hydrography and Marine Meteorology" for January 1893); or else instructions tending in this direction might be given by the German Lloyd to the agents of the Marine Association.

II.—THE SCREENING OF SIDE LIGHTS.

A thorough examination of this question has convinced us that the instructions issued by the Board of Trade constitute a substantial improvement. Our reasons for this opinion will be found in the following considerations:—

The substance of the Imperial Ordinance of the 7th January 1880, on the construction and screening of side lights, is that "side lights must be visible for at "least two miles, and must show a uniform and un- "broken light over an arc of the horizon of 10 points "of the compass, from right ahead to two points abaft "the beam. These lights must be fitted with inboard "screens projecting at least 1 metre forward of the "light, and so fixed as to prevent the light from being "seen across the bow."

This rule, which is based on an international agreement on the subject of the construction and screening of side lights, is in itself perfectly clear, and could not possibly cause misunderstanding if it were practicable to carry it out exactly with existing side lights. We have, however, to take into consideration the construction of the lantern and of the lamp inside it. In accordance with the law of the diffusion of light in straight lines, every illuminated point can be seen from any other point if no opaque body intervenes in the straight line which connects them. In the case of the lamps in ships' lanterns, however, we have not got to deal merely with a single illuminated point, but, not to speak of the diffused light, with a series of illuminated points; and all these points, whether they are arranged in circles, as is the case with round burners, or in straight lines, as is the case with flat burners and electric lamps, send out direct rays.

To thoroughly investigate this question of screening it is necessary to discuss the construction of the lanterns and the screening of the lights separately.

(a.) *Construction of the Lanterns.*

In side lights different kinds of burners can be distinguished. The commonest are—

1. Round burners for petroleum, at least 25 millimetres in diameter, as prescribed in the English regulations.
2. Round burners for colza, at least 45 millimetres in diameter, as prescribed in the English regulations.
3. Flat burners (Imperial Navy) 33 millimetres broad.
4. Incandescent electric lamps.

Now the text of the Ordinance requires that the full and unbroken light shall show from right ahead to two points abaft the beam, *i.e.*, from A to B in Fig. 1.* (This and the following plates represent the starboard lamp.) Therefore the lens of the lantern must extend at least from *a* to *b*, so that the full light may show over an arc of 10 points, and all the illuminated points of the burner may be seen within this arc. Further, the centre of curvature of the lens must be opposite the middle point of the burner. But it must be observed that the outer points of the wick also send their rays to $A_1$ and $B_1$, so that the light, though perhaps not in its full volume, is visible over an arc of the horizon of about 12 points, an angle which, according to the report of Captain Maack, has been actually observed in many cases. And this is the only way in which the lights can be arranged if they are to comply with the Imperial Ordinance; if they are arranged differently they will not show a full and uniform light over an arc of 10 points.

In the form of the side lights, considerable variations are often found. These variations make it appear that

WYMAN AND SONS LTD LITH. 9/60.5.95.

the manufacturers start with the erroneous idea that the interior of the lantern is one large source of light, and that it is only necessary to place the lamp somewhere inside the lantern in order to produce the desired effect. In Fig. 2, for example, the lamp is placed at L, and the light will show over the arc A B; the rays, however, will not run parallel to the keel, but will cut the line of the keel projected ahead of the ship, and will not reach to two points abaft the beam. But if the lamp is placed instead on the dotted line at $L_1$, the full uniform light will show from $A_1$ to $B_1$; the arc is still only 10 points, but it now extends from right ahead to two points abaft the beam, and the lanterns comply with the requirements of the Regulations.

A pattern of lamp which is as often met with is that represented in Fig. 3. Here the light shows over a much larger angle than 10 points, including the two points abaft the beam. The rays from the outer edge *a* of the wick (Fig. 3) extend over the arc from $A_1$ to $B_1$, that is over a much greater angle than 10 points. This, however, is not a serious fault, since the rays which pass ahead of the light must be regulated by means of a screen. Even the lantern in Fig. 2 can be made use of, for it can be so turned as to show over the two points abaft the beam. In practice, however, attention is not usually paid to this point when the lights are being fixed, so the lanterns should be all so arranged that their after sides stand at right angles to one another, and that one of these sides is exactly parallel to the line of the keel.

In placing the lamp in the lantern, care must also be given to the position of the spherical reflector at the back of the lantern (*see* R in Fig. 1). The centre of the burner must be opposite to the centre of the reflector, and the reflector must be large enough to reach from *c* to *d* in Fig. 1, so that the rays may be seen in their full strength over the above-mentioned arc of 10 points. In many cases the reflectors are small and damaged, and can only be expected to show properly over an arc of from two to six points.

Lanterns of this type, with improperly placed lamps and defective reflectors, are still manufactured and used.

Still further variations in the patterns of side lights might be adverted to, but the extreme cases already dealt with are sufficient to show that all lanterns do not comply with the legal requirements. The points to be observed in examining a lantern are not merely whether the illuminating power is sufficient, and whether the ventilation of the lamp, and its security against being blown out by the wind, and its general working, are satisfactory; but also whether the position of the lamp in the lantern has been rightly chosen, and will secure that the rays from the lantern fall within the prescribed angle. This object will be best attained by direct measurement of the angle at the lantern, and not by observation of the actual rays, because in observing the rays it is difficult, without special apparatus, to distinguish the reflected rays $A_1$ $B_1$ (Fig. 3), from the direct rays A and B.

We assume that the instructions for testing lanterns which are contemplated by the Imperial Marine authorities will take into account these errors in construction to which we have referred.

To sum up:—

1. The after sides of the lanterns must stand at right angles to one another, and one of these sides must be exactly parallel to the middle line of the ship.
2. The lamp must be so placed in the lantern that all the rays from the wick can throw an uninterrupted light through the lens parallel to the keel ahead of the ship, and as far as two points abaft the beam. The way in which this is to be done is shown in—
   Fig. 4, for petroleum and electric light.
   Fig. 5, for colza.
   Fig. 6, for flat burners.

A larger arc than 10 points of the compass is admissible, but the excess must be in the direction [illegible] of the lamp, and not abaft the beam (Fig. 3).

[illegible]

The [illegible] with the line of the keel by a line drawn from [illegible] be about 4°.

A [illegible] regulation of the Board of Trade opposition has been raised on various sides. (*See* a series of articles in the *Nautical Magazine* for 1893, pp. 118, 200, 242, 245, 421, 497, 740, 940: Proceedings at the General Meeting of the German Nautical Union, 1894, p. 75 *sq.*; the report of the Columbus Shipping Union of Bremen, &c., &c.) The Netherlands Government even sees in this rule an infringement of the International Regulations, and is of the opinion that Netherlands judges would condemn ships in collision cases whose lanterns were screened in this manner. Further, eminent English counsel describe the Order as a "rule "that is in direct conflict with the International Rules." (*See* Blue Book C.–6869.) From the following explanations it will nevertheless be seen that this rule is simply intended to secure the carrying out of the Regulations. Apr. 2, No. 11

In most cases the critics take up the position that the 4° angle is much too large, and that it would be, therefore, better to leave things as they were under the old system.

But, when we consider clearly what would happen if the angle were made as small as possible, *i.e.*, if the screen were fixed parallel to the keel in a line with the inner edge of the wick (Fig. 7), we find that with screens 1 metre long, the outermost direct rays from point (*a*) of the wick will be visible across the forward end of the screen, and that with—

a round wick 25 millimetres in diameter the angle will be about 1½°.
a round wick 44 millimetres in diameter the angle will be about 2½°.
a flat wick 33 millimetres broad the angle will be about 2°.

The angle cannot be reduced beyond this point, because a smaller angle would render it impossible to comply with the requirement of the Regulations as to the light being uniform.

On the other hand, if we examine the system of screening now prevalent on board the great majority of non-English ships, we find that it is effected by means of screens which are ordinarily fixed at a distance of 100 to 140 millimetres from the outer edge of the wick (Fig. 8), and we reach the conclusion that in the majority of non-English ships the angle is from 6° to 8°, that is, from one-half to three-quarters of a point.

It is clear that the critics who think 4° too large, and prefer to retain the old system, are not thoroughly aware of this fact. In any case they proceed on the erroneous idea that the present angle is a little over nil, and at all events is under 4°, whereas in reality it is nearly twice that angle.

It is not possible to say with absolute exactness what the best angle would be, but the numerous discussions and reports on this subject entitle us to assume that the angle of 6° or 8°, which is at present actually found on most non-English ships, is far too large, and that a smaller angle of 3° to 4° would better tend to the safety of navigation.

We should not hesitate to recommend the extension to German ships of screening regulations on the lines of those issued by the English Board of Trade, if it were not for the fact that at the present moment these regulations are meeting with considerable opposition in England. We therefore propose to wait in order to see whether any valid technical arguments will be brought forward which will induce England to repeal these Instructions. Failing that, it is our opinion that the Government should be moved to add the following interpretative clause to the Imperial Ordinance of the 7th January 1880.

"The line drawn from the outer edge of the wick through the foremost edge of the screen shall form an angle of approximately 4° with the line of the keel."

### Concluding Remarks.

Coming now to the mode of carrying out this regulation, we notice that the necessary alterations in the existing screens could be made without the least difficulty.

It is only necessary to fix on the forward end of the screen (as shown in dotted lines at A in Fig. 8) a piece of wood so arranged as to be 70 millimetres distant from the outside edge of the wick, where the screen is 1 metre long, and proportionately further away with screens of greater length.

We attach two full-sized* diagrams, the upper one of which illustrates the usual method of screening followed at present, and the lower one the method of screening to an angle of 4°. In new ships, the screen

* Note.—These diagrams have apparently been reduced. *See* Plate X.

App. 2, Nos. 10 and 11.

should be arranged exactly in the manner shown in the lower diagram.

Finally, we must point out that the distance of the lamp from the inner side of the lantern is not the same in all cases, because all lanterns are not made on a uniform plan. Consequently, when a lantern fails and has to be replaced by another of a different make particular care has to be taken to see that the outer edge of the wick in the second lantern is situated at the proper distance from the screen.

This difficulty would be best avoided if the Imperial Marine authorities, on the strength of their great experience of the construction of side lights, would prepare a pattern which should serve as a model to the manufacturers. The manufacturers would then cease to work disconnectedly, each according to his own pattern, and would eventually produce lanterns not only complying with the Regulations, but differing from one another so slightly that no alteration in the screens would be necessary if the lanterns happened to be changed.

German Lloyd.

No. 11.—Report by the Assistant Superintendent of Experiments at Shoeburyness on the Experiments of October 1893.

17th October 1893.

*Subject.—Trial of Ships' Side Lights, Report on.*

These tests were carried out in the presence of several members of the Rule of the Road Committee.

On the first night (October 12th) the weather was unfavourable, the atmosphere being thick. The tests on this night were confined to distances of 2,000 yards and under, and one pair of lamps were used throughout. This pair was marked H, particulars as follows:—

| Maker. | Wicks—No. | Chimney. | Lens. | Oil. |
|---|---|---|---|---|
| Starnes and Sons - | 1 | Yes - | White dioptric with coloured slide. | Paraffin. |

The result of the observations is shown in the attached Tables marked A and B.

On the second night (October 13th) four pairs of lamps were subjected to trial, and the pair tested on 12th October were exhibited in a conspicuous position, showing about five points, to serve as a standard for comparison.

The lamps tested were marked A, E, F, and Admiralty respectively, particulars as follows:—

| Maker. | Wicks—No. | Chimney. | Lens. | Oil. |
|---|---|---|---|---|
| A: Andreasen - | 1 | Yes - | White dioptric with coloured slide. | Paraffin. |
| E: Ridsdale - | 2 | Yes - | Dioptric coloured glass. | „ |
| F: W. and A. Nunn | 1 | Yes - | Fish bowl, coloured glass. | „ |
| Admiralty - - | 2 | No - | White dioptric with coloured slide. | Colza. |

As a preliminary experiment the four green lights were exhibited at the same time, all showing about five points. It was noted that the green of the Admiralty lamp appeared lighter than the others at short distances, but this difference became less marked as the distance increased.

Their relative intensity was observed at one mile (2,000 yards), and found to be as follows:—

Best - Admiralty.
2nd - H: Starnes' lamp, used as a standard.
3rd - {A: Andreasen, E: Ridsdale,} about equal.
5th - F: Nunn, hardly visible.

Same lamps again observed in same positions at 2 miles (4,000 yards).

Their relative intensities compared, allotting a value of 10 to the best lamps.

Results:

Best - Admiralty intensity valued at 10.
2nd - H: (Starnes, used as a standard for the observations which followed) - „ 8.
3rd - {A.: (Andreasen) E: (Ridsdale)} „ 5.
5th - F: (Nunn) - - „ 2.

The results of the further observations on this night are shown in attached Tables C and D.

Fred. Elmslie, Major R.A.,
Asst.-Supt. Expts., for Supt. Expts.

A. Results of Testing Ships' Side Lights at Shoeburyness.

| Date of Test. | Distinguishing Mark on Lanthorn. | | Colour of Light. | Angle of Screening. | Appearance of the Light when viewed from Ahead, and at 5 Points from Ahead, at a Distance of 1,000 Yards from the Lamps. | | | |
|---|---|---|---|---|---|---|---|---|
| | | | | | Ahead. | | Five Points from Ahead. | |
| | | | | | Intensity. | Colour. | Intensity. | Colour. |
| 12th October 1893. | Lanthorns marked "H." Maker's name J. S. Starnes and Sons. Lenses white dioptric with coloured slides. One wick, with chimneys. | H. P. - | Red - | 1° - - | Fair - - | Good red - - | Very good - | Good luminous red. |
| | | H. S. - | Green | 1° - | Indifferent - | Clear green - | Good, but not nearly so bright as the red. | Clear green. |
| | | | | | There is a marked difference in the size of each light when showing at 5 points and right ahead screened to 1°. In the latter case the light appears less than half the intensity that it does in the former. | | | |
| | | H. P. - | Red - | 2° - - | Smaller than at five points. | Good. | | |
| | | H. S. - | Green | 2° - | Do. do. | Do. | | |
| | | H. P. - | Red - | 3° - - | Judged as good as at 5 points. | Do. | | |
| | | H. S. - | Green | 3° - | Judged slightly smaller than at 5 points. | Do. | | |
| | | H. P. - | Red - | 4° - | As good as at 5 points. | Do. | | |
| | | H. S. - | Green | 4° - - | Do. do. | Do. | | |

Does the light show a uniform and unbroken light in colour and power ahead when screened to an angle of 1°, 2°, 3°, and 4°, as compared with its colour and intensity when exhibited to the observer at an angle of 5 points?—No, neither light at this distance.

If it is not uniform, in what respects is its uniformity deficient, and at what angle of screening?—Screened to 4° both lights remain uniform. Screened to 3° the red lamp remained uniform, but the green was thought slightly smaller. Screened to 2° both lamps showed smaller, while at 1° they were markedly smaller than when showing at 5 points.

Notes regarding the Condition of the Weather and Lamps at the time the Tests were made.

Weather.—Calm. Low-lying haze on sands. Nore Light and Sheerness lights quite invisible. Unfavourable for long distance observations.

Lamps.—Were 30′ apart from outside to outside of wick. Both burnt brightly throughout, but flame of green was fish-tailed and not so level as that of the red. The centre of the flame appeared slightly below the centre of the lens.

The theoretical distance at which direct rays should cease to be visible to the right and left of the middle line is shown in *red* alongside the observed distances. This theoretical distance was not known beforehand to the observers who were guided solely by the appearance of the lights. The distances at which the two lights ceased to be practically visible was noted by separate parties, one for either flank.

In almost all cases reflected rays from the lens were visible for some distance beyond the points noted, and it was difficult to fix the exact spot of practical disappearance within a yard or two. For instance, at 1,000 yards slight rays from the red lamp, screened to 1°, could be seen through glasses up to 150′ from the middle line.

Notes regarding the Condition of the Weather and Lamps at the time the Tests were made.

Weather.—Calm. Low lying haze on the sands. Nore Light and Sheerness lights quite invisible. Unfavourable for long distance observations.
Lamps.—Were 30′ apart [illegible] outside to outside of wicks. Both burnt brightly throughout, but flame of green was fish-tailed and not so level as that of the red. The centre of the flame appeared slightly below the centre of the lens.
Measurements.—All measurements taken from the centre line midway between the two lamps.

| | Ridsdale Lamps. E. P. | Red | 4° | Do. = (7) | | | |
| | Ridsdale Lamps. E. S. | Green | 4° | Do. = (7) | | | It is noteworthy that this green lamp did not show so well at 5 points as it did right ahead when screened at 3° and 4°. |
| | "H" Lamps. H. P. | Red | | | | Judged = (10) | Very good. |
| | "H" Lamps. H. S. | Green | | | | Do. = (8) | |
| | "H" Lamps. H. P. | Red | 2° | Perfectly visible. Could not be allotted marks owing to there being now no standard of comparison. | Colours good. | | |
| | "H" Lamps. H. S. | Green | 2° | | | | |
| | "H" Lamps. H. P. | Red | 3° | Both slightly larger than when screened to 2°. | | | |
| | "H" Lamps. H. S. | Green | 3° | | | | |
| | "H" Lamps. H. P. | Red | 4° | Same as at 3°. | | | |
| | "H" Lamps. H. S. | Green | 4° | | | | |

Does the light show a uniform unbroken light in colour and power ahead when screened to an angle of 1°, 2°, 3°, and 4° as compared with its colour and intensity when exhibited to the observer at an angle of 5 points?—None of the lights tested did this.

If it is not uniform, in what respects is its uniformity deficient, and at what angle of screening?—None of the lights appeared to attain as great intensity right ahead at any angle of screening as they did at 5 points, with the exception of the green "E" lamp, which showed better right ahead when screened 3° and 4° than at 5 points. The angle of screening also made a difference in the uniformity of the light, the 1° screen greatly reducing its size.

Notes regarding the Condition of the Weather and Lamps at the time the Tests were made.

Weather.—Dark night—no moon—clear—Nore and Mouse Lights, Sheerness lights, and lights in Channel all visible. Very favourable for long distance observations.

Lamps.—Were 30′ apart from outside to outside of wick. All in good order and correct.

## No. 12.—ORDER in COUNCIL of JANUARY 30, 1893.

At the COURT at OSBORNE HOUSE, ISLE OF WIGHT, the 30TH DAY of JANUARY, 1893. Present, THE QUEEN'S MOST EXCELLENT MAJESTY IN COUNCIL.

Whereas, by an Order in Council made in pursuance of the Merchant Shipping Act Amendment Act, 1862, and dated the 11th day of August, 1884, Her Majesty on the joint recommendation of the Admiralty and the Board of Trade was pleased to direct that on and after the 1st day of September, 1884, the Regulations contained in the Schedule thereto should, so far as regards British ships and boats, be substituted for the Regulations contained in the First Schedule to an Order in Council made as aforesaid, and dated the 14th day of August, 1879.

And whereas by two Orders in Council made in pursuance of the said Act, and on such joint recommendation as aforesaid, and dated respectively the 30th day of December, 1884, and the 24th day of June, 1885, certain modifications and additions were made to the said Regulations contained in the Schedule to the said recited Order in Council of the 11th day of August 1884, as regards British fishing vessels and boats.

And whereas by another Order in Council made in pursuance of the said Act and on such joint recommendation as aforesaid, and dated the 18th day of August 1892, certain modifications and additions were made to the said Regulations contained in the Schedule to the said recited Order in Council of the 11th August 1884, as regards steam pilot vessels.

And whereas by the said Regulations contained in the Schedule to the said Order in Council of the 11th day of August, 1884, it is amongst other things provided as follows—

Art. 3.—A sea-going steam ship when under way shall carry—

(*a.*) On or in front of the foremast, at a height above the hull of not less than 20 feet, and if the breadth of the ship exceeds 20 feet, then at a height above the hull not less than such breadth, a bright white light, so constructed as to show an uniform and unbroken light over an arc of the horizon of 20 points of the compass, so fixed as to throw the light 10 points on each side of the ship, viz., from right ahead to two points abaft the beam on either side, and of such a character as to be visible on a dark night, with a clear atmosphere, at a distance of at least five miles.

(*b.*) On the starboard side, a green light, so constructed as to show an uniform and unbroken light over an arc of the horizon of 10 points of the compass, so fixed as to throw the light from right ahead to two points abaft the beam on the starboard side, and of such a character as to be visible on a dark night with a clear atmosphere, at a distance of at least two miles.

(*c.*) On the port side, a red light, so constructed as to show an uniform and unbroken light over an arc of the horizon of 10 points of the compass, so fixed as to throw the light from right ahead to two points abaft the beam on the port side, and of such a character as to be visible on a dark night, with a clear atmosphere, at a distance of at least two miles.

(*d.*) The said green and red side lights shall be fitted with inboard screens projecting at least three feet forward from the light, so as to prevent these lights from being seen across the bow.

Article 15.—If two ships under steam are meeting end on, or nearly end on, so as to involve risk of collision, each shall alter her course to starboard, so that each may pass on the port side of the other.

This article only applies to cases where ships are meeting end on, or nearly end on, in such a manner as to involve risk of collision, and does not apply to two ships which must, if both keep on their respective courses, pass clear of each other.

The only cases to which it does apply are, when each of the two ships is end on, or nearly end on, to the other: in other words, to cases in which by day, each ship sees the masts of the other in a line, or nearly in a line, with her own; and by night to cases in which each ship is in such a position as to see both the side lights of the other.

It does not apply by day, to cases in which a ship sees another ahead crossing her own course; or by night, to cases where the red light of one ship is opposed to the red light of the other, or where the green light of one ship is opposed to the green light of the other, or where a red light without a green light, or a green light without a red light, is seen ahead, or where both green and red lights are seen anywhere but ahead.

And whereas there has been doubt or misapprehension concerning the effect of the said two articles; and whereas the Admiralty and the Board of Trade have jointly recommended to Her Majesty to make the following additions to the said Regulations for the purpose of explaining the said recited articles, and of removing the said doubt or misapprehension:

Now, therefore, Her Majesty, by virtue of the powers vested in Her by the said Act, and by and with the advice of Her Privy Council, is pleased to direct that, from the date of this Order, the Regulations contained in the Schedule to the said Order in Council of the 11th day of August 1884, shall be further modified by the addition to the said recited Article 3 of the provisions contained in the Schedule hereto.

HERBERT M. SUFT.

App. 2, Nos. 12 and 13.

SCHEDULE.

(*e.*) To ensure that the red and green side lights shall show an uniform light from right ahead of the ship to two points abaft the beam on the port and starboard sides respectively, and shall not show across the bow of the ship itself, the said lights must be fixed and the screens fitted so that the rays from the red and green lights shall cross the line of the ship's keel projected ahead of the ship at a reasonable distance ahead of the ship.

With regard to all vessels whose lights are inspected by the officers of the Board of Trade, the red or green side light will not be deemed to be fixed and fitted in accordance with the Regulations unless it is so fixed and screened that a line drawn from the outside edge of the wick to the foremost end of the inboard screen of such light shall make an angle of 4 degrees, or as near thereto as may be practicable, with a line drawn parallel with the keel of the ship from the outside edge of the wick.

---

## No. 13.—Further MEMORANDA on the SCREENING of SIDE LIGHTS by SIR DIGBY MURRAY.

### A.—*Colour as affecting the Distant Visibility of the Red and Green Lights, and also the Transverse Distance to which they may be Visible from the Middle Line.*

#### (1.) IN CLEAR WEATHER.

*Red.*—55 to 65 per cent. of the white light is absorbed when covered by a red plate, *i.e.*, only $\frac{3}{5}$ of the light remains.

*Green.*—75 to 85 per cent. of the white light is absorbed when covered by a green plate, *i.e.*, only $\frac{1}{5}$ of the light remains.

#### (2.) IN THICK WEATHER.

*Red.*—From 50 to 60 per cent. of the white light is absorbed; in this case the red is absorbed in smaller proportion than the white.

*Green.*—The green light, on the contrary, is absorbed in a greater proportion than the white, probably increasing from 75 and 85 per cent. to 80 and 90 per cent.

There was a striking confirmation of this in the experiments of June 1891, when a green light which was visible at 43 ft. 9 in. from the middle line at a distance of 815 feet from the lights was only visible 42 ft. 3 in. at a distance of 1,200 feet from the lights, although theoretically it ought to have remained visible for double that distance; the weather on this occasion was not very thick, but the observers were aware, owing to the fluctuating brilliancy of the lights, that light mist was occasionally being driven across the face of the lamps.

From the above it is evident that the visibility of the lights from the middle line will fluctuate, not only with the variations of colour, both of the red and also of the green lights, but also under different atmospheric conditions.

It is also certain that they will vary—

(*a.*) With the description of lens.

(*b.*) With the construction of the lanthorn, the position of the wick with reference to the chord of the arc, and more especially with its position in the lanthorn, *i.e.*, according as its centre is the centre of curvature of both the lens and the reflector, or according to the extent to which it deviates from that position.

They will also vary with the difference of trimming, the difference of compression of the wicks, and with the ventilation of the lanthorn.

On these points the Committee may wish to hear expert evidence, as I am only quoting from Mr. Kenward as to the effect of colour.

If it is suggested that the present angle of 4° should be reduced, it will, I think, be for consideration whether the Board of Trade should not have statutory power to prohibit the use of plano-convex and fish-globe lenses, and also to insist on some general principles of construction. The trade should be interfered with as little as possible, and the makers might be invited to assist in framing the rules.

Before absolutely condemning plano-convex and fish-globe lenses it would be desirable to test them by further experiment.

On the allegation that an angle of 4° is productive of danger, I propose to treat separately.

### B.—*Alleged Danger of Screening the Side Lights to an Angle of 4°.*

The regulations are as follows:—

Art. 15. If two ships under steam are meeting end on, or nearly end on, so as to involve risk of collision, each shall alter her course to starboard, so that each may pass on the port side of the other.

This article only applies to cases where ships are meeting end on, or nearly end on, in such a manner as to involve risk of collision, and does not apply to two ships which must, if both keep on their respective courses, pass clear of each other.

The only cases to which it does apply are, when each of the two ships is end on, or nearly end on, to the other; in other words, to cases in which, by day, each ship sees the masts of the other in a line, or nearly in a line, with her own; and by night, to cases in which each ship is in such a position as to see both the side lights of the other.

It does not apply, by day, to cases in which a ship sees another ahead crossing her own course; or by night to cases where the red light of one ship is opposed to the red light of the other, or where the green light of one ship is opposed to the green light of the other, or where a red light without a green light, or a green light without a red light, is seen ahead, or where both green and red lights are seen anywhere but ahead.

It may be a matter of doubt as to what is meant by "ahead," and this question is at present in a most unsatisfactory condition (*see* Marsden's "Collisions at Sea," pages 424–425). For the purpose of this discussion, I will assume that no vessel which is broader on either bow of another vessel than 4° is to be considered as "meeting end on, or nearly end on." It is quite clear that when any vessel is steering directly for any other vessel, all her lights will be seen by that vessel, no matter what her bearing may be.

But it is expressly forbidden to port to these vessels under Article 15, when their lights are seen anywhere but ahead. Now let us suppose that a vessel is always to port when both side lights of another vessel are visible at an angle not exceeding 4° on either bow, and when, in the case of steamships, the masthead light is also visible. I wish to select for the purpose of this consideration the position in which the alleged danger is the greatest, and that must evidently be in the case where the departure from the original course is most considerable, and where the transverse distance to be traversed under port helm is the greatest.

It is quite evident that this will not be the case when two vessels see all the lights respectively of one another on their port bow, as if they port they will never cross the track one of another.

When two vessels see each other's lights on the starboard bow, it is quite clear that the most crucial position is when the vessels bear 4° from each other, and also when their courses are parallel to one another, as if their courses converge the transverse distance to be crossed under port-helm will be less.

The accompanying diagram* shows this extreme position.

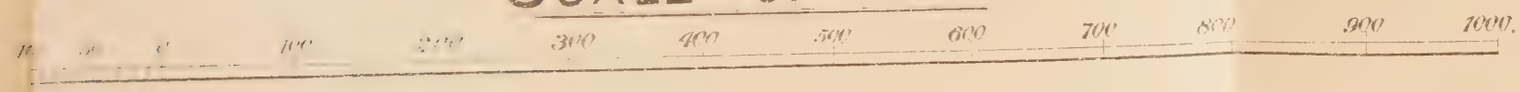
If the vessels forge another ship's lengths ahead, neither of them would see all the lights of the other.

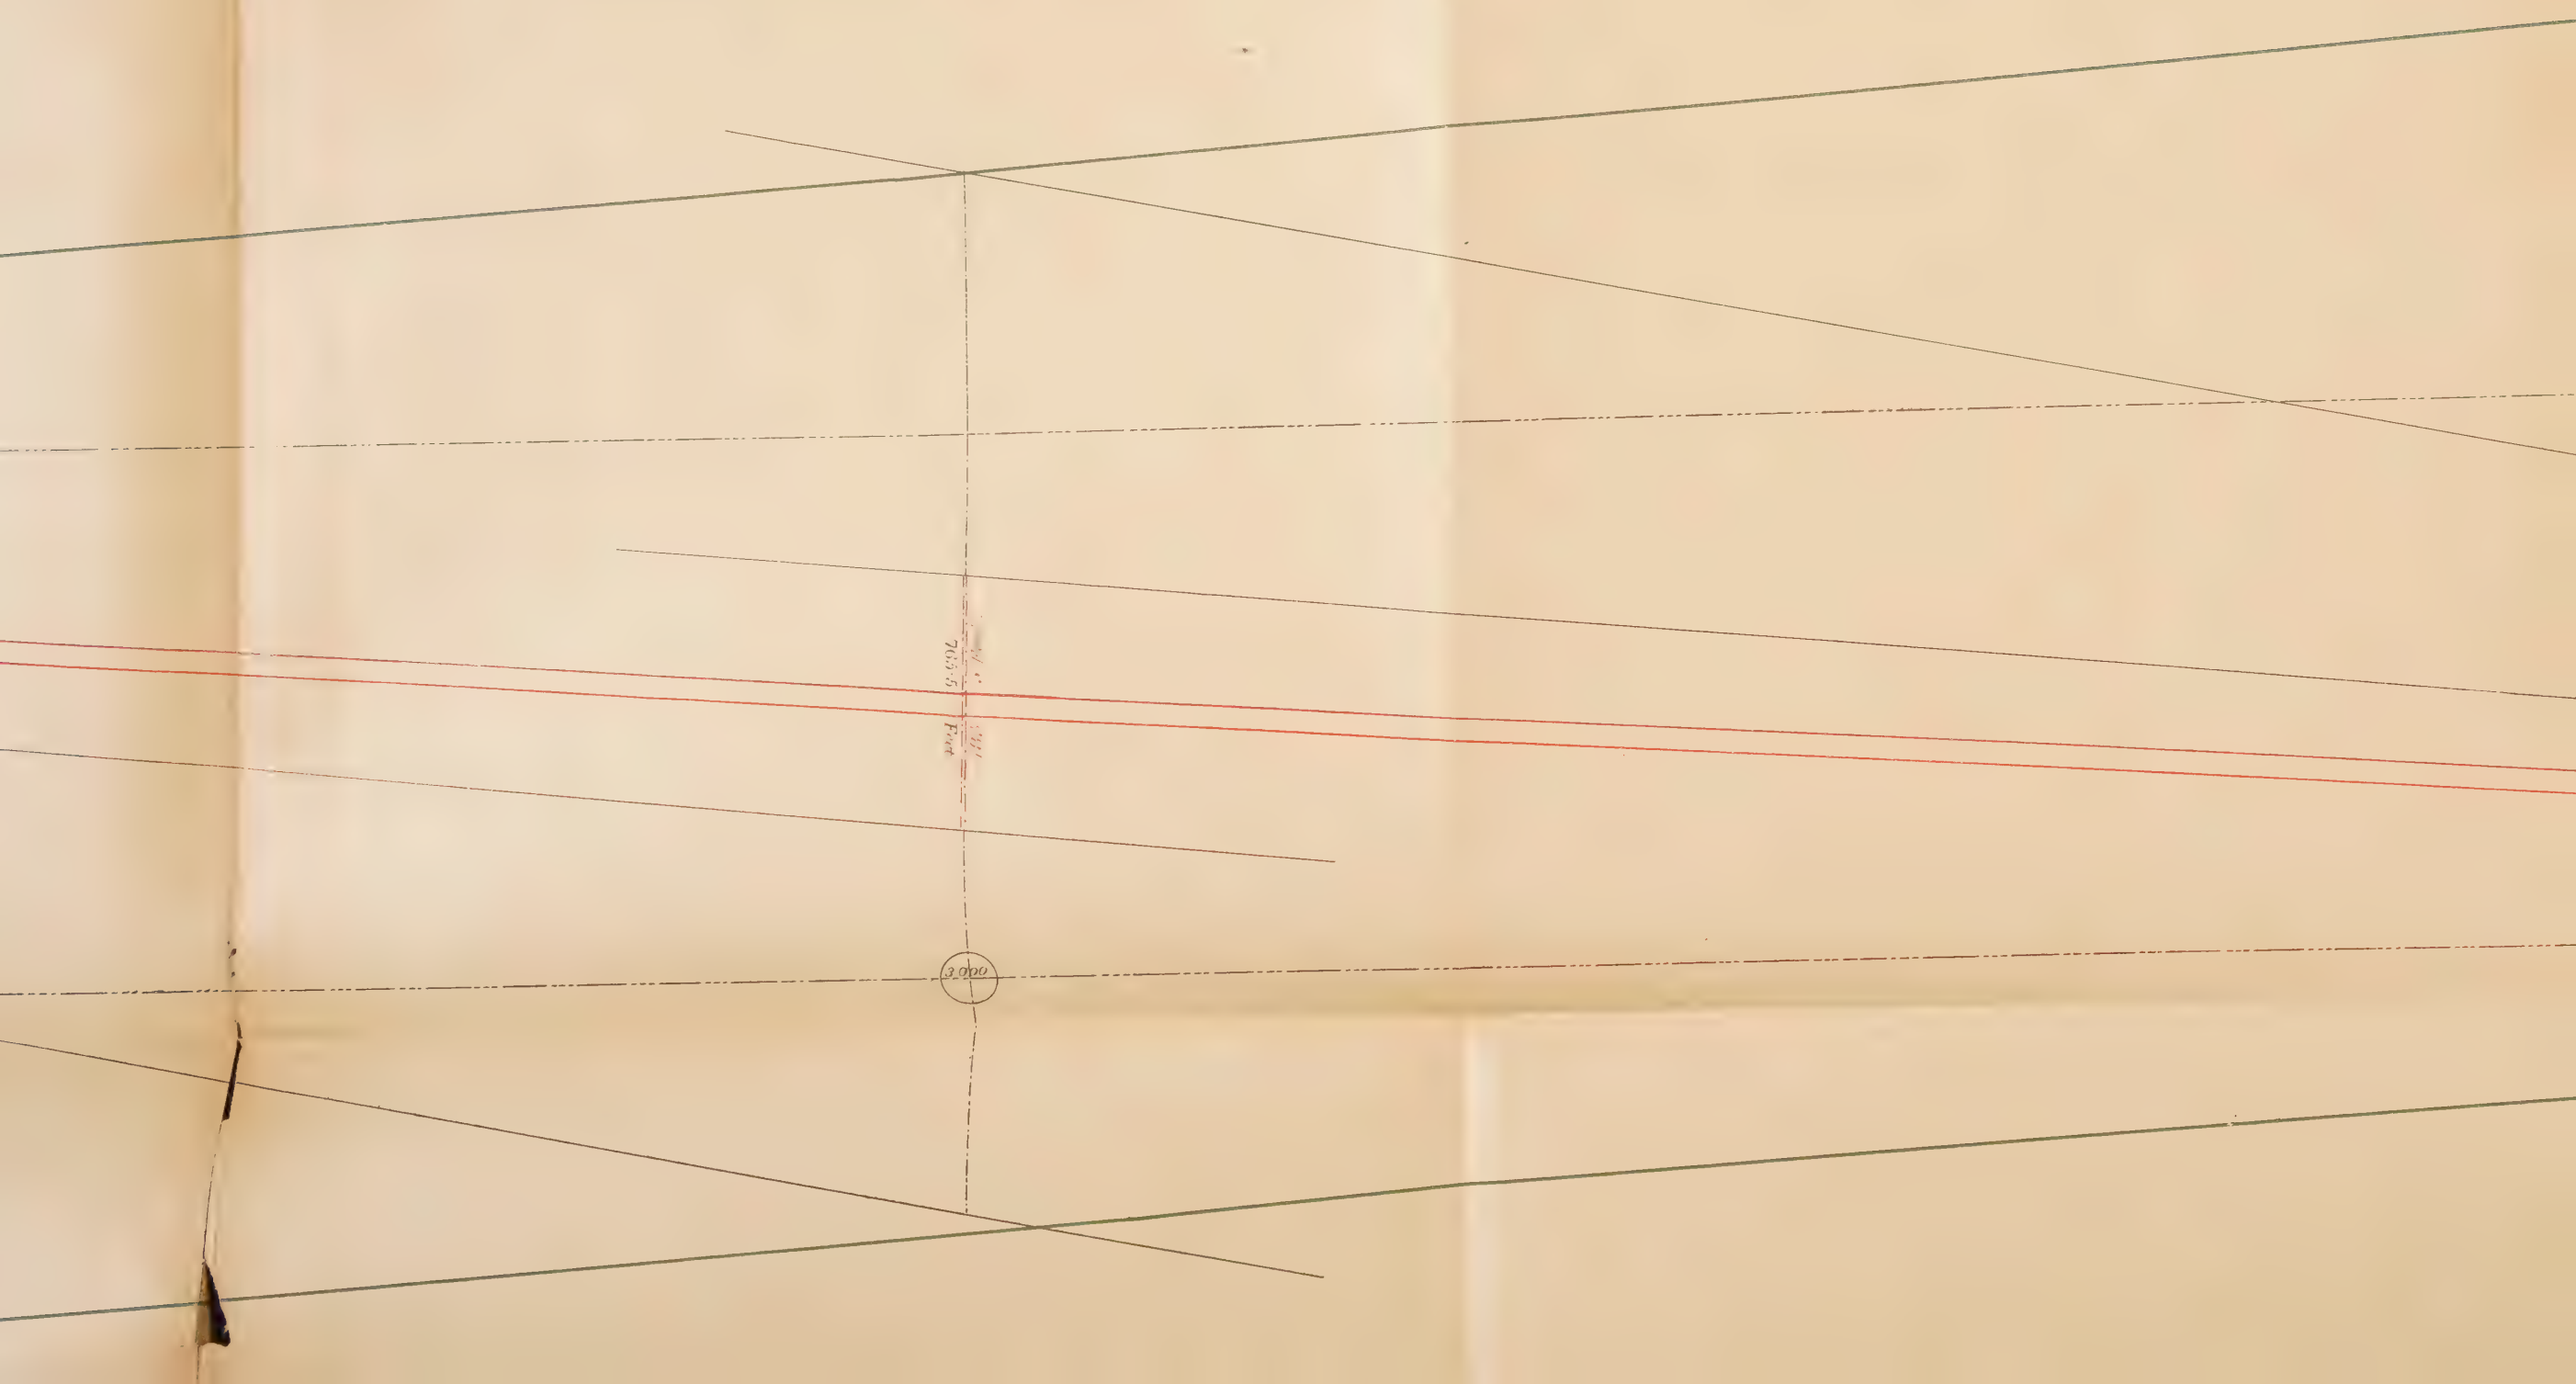
In the diagram the ships are 6,000 feet, or one sea mile apart; but I will in addition give the exact figures applicable both to that distance, to half that distance, *i.e.*, half a sea mile, and to a quarter that distance, *i.e.*, a quarter of a sea mile.

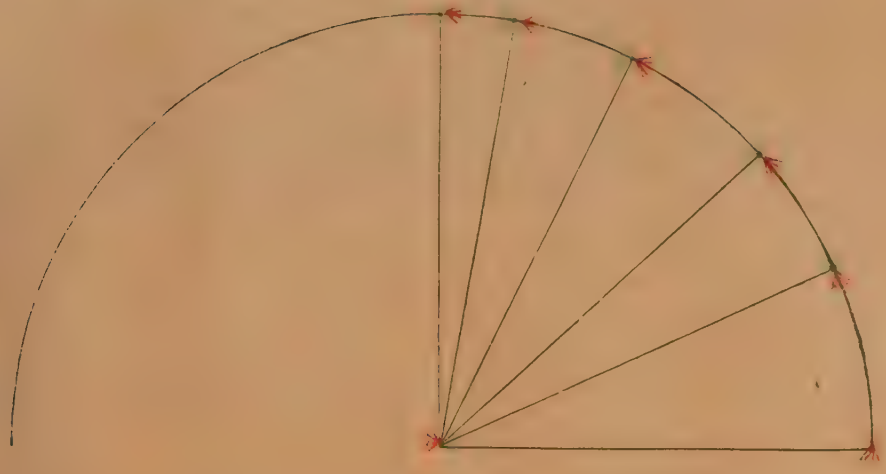
* Plate XI.

*Diagram showing it is not dangerous to screen lights to an angle of 4°*
*If the two ships shown in the diagram port only half a point they pass clear of one another; if they port one point they pass 765·5 feet clear of one another.*

SCALE OF FEET.







Before referring to the diagram, I think I may safely say that no officer in charge of a vessel's deck would be likely to port half a point only; to clear another vessel he would rarely port as little as one point, unless the movements of his vessel were complicated by the proximity of other vessels or the land.

In the diagram I have supposed both vessels to have equal speed, but the result will not be affected by difference of speed as the smaller departure made by the slower vessel will be counterbalanced by the larger departure of the faster vessel.

I do not wish it to be understood, because I am showing the exact results on the diagram, that I am therefore advocating small helm. I think, when circumstances permit, helm should be given at the earliest possible moment, and plenty of it.

In conclusion, I may say that I cannot see any possible danger in screening to an angle of 4°, and that the Board of Trade practice for the last 30 years has failed to indicate it.

D. Murray.

November 7th, 1893.

Tabulated Statement to be attached to Diagram (X).

| Distance from the Lights. | Position of the Vessels with reference to each other. | Theoretical Distance between the Paths of the two Vessels. | Distance between the Vessels when they are abeam of one another, supposing their Speed to be equal, and that they have both ported ½ point. | Distance between the Vessels when they are abeam of one another, supposing their Speed to be equal, and that they have both ported one point. | Remarks. |
|---|---|---|---|---|---|
| | | Feet. | Feet. | Feet. | |
| One sea mile (6,000 feet). | 4° on each other's starboard bow and steering parallel courses. | 404·5 | 180·5 | 765·5 | The results will be approximately proportional for all distances, but the shorter the distance the larger will be the amount of helm which is desirable. |
| Half of a sea mile (3,000 feet). | Ditto - - | 194·8 | 99·2 | 390·2 | |
| 1,500 feet - - | Ditto - - | 89·9 | 57·0 | 202·7 | |

C.—*Danger of screening Lights to a smaller angle than 4°.*

I have shown above that it is not dangerous to screen side lights to an angle of 4°, but that, on the contrary, even in the extreme case where ships are steering parallel courses and bear 4° on each other's starboard bow, it is perfectly safe to port, and that an alteration of course of one point only will enable them to pass abundantly clear of one another.

I now propose to show that to screen the lights to a smaller angle than 4° is distinctly dangerous, as if ships are approaching one another at an angle sufficiently large to prevent both side lights of each ship being seen by the other, but which is small relatively to the direction of each ship, there is no article in the present "Regulations for preventing Collisions at Sea" which applies to them.

They are not crossing ships under Article 16, and even if it was held that this article might be so strained as to apply to two ships on each other's starboard bow, it could not possibly apply to ships approaching one another at the same angles on each other's port bow.

The late Mr. Thomas Gray's verses do not apply to either of these cases, "Green to Green, Red to Red, Perfect safety, Go ahead." On the contrary, if their lights are screened to an angle of 2° and they follow this injunction and keep their courses, collision is practically inevitable, and even if screened to 3° they will under many conditions pass so unpleasantly close as to involve very grave danger of collision.

In Figure 1 of diagram (Y) two ships are shown, A and B. A is a steamship 4° on B's starboard bow, distant ¼ mile, and with her course converging 1½° towards B's, which of course the officer in charge of B's deck is unaware of.

B is steering due W. and A is steering E. 1½° S. As neither of them see the two side lights of the other they presumably keep their course, and if they are of equal speed they will be only distant some 45 feet from each other at the middle distance marked X (always supposing that the ships steer as straight at sea as they can be made to on paper); but if, as will often happen, A has double the speed of B, then the two ships will be distant only 37 feet in the position marked Y.

Figure 2 of this diagram shows two ships A and B steering respectively E. 1½ south and W. 1½ north, *i.e.*, parallel courses; then, no matter what their relative speeds may be, they will, provided they both maintain their course, pass about 25 feet from one another, or so near as to be practically in collision.

App. 2, No. 13 and 14.

It may and probably will be argued that no ship is steered with such absolute accuracy as to admit of only one light being constantly seen at such small angles. This I admit, but what is the officer of the watch of a ship to do when he only occasionally sees a flickering of the second side-light? The Regulations do not provide for this, and, moreover, it must be remembered that the green light will not in the majority of cases be seen at the theoretical distance from the middle line. This the experiments of Mr. Samson and myself, as well as those recently conducted at Shoeburyness, abundantly prove.

In conclusion, I would strongly urge upon the Committee that the side lights of merchant ships cannot safely be screened to a smaller angle than 4°. Should they be altered, and the angle reduced, I cannot too strongly press the necessity of again altering the "Regulations for preventing Collisions at Sea," so as to guard against the dangers which are sure to arise from such a reduction, as well as to indicate to commanders of ships what their action ought to be under the circumstances which I have now indicated.

In diagram (Y) the steamships are represented as having a length of 240 feet and a beam of 30 feet. Vessels of great beam, say, of 50 to 60 feet, if approaching one another as shown in Figure 2 of the diagram, would absolutely be in collision if they maintained their course. *See* diagram (Z).

D. Murray.

November 21st, 1893.

No. 14.—Memorandum by Mr. Samson on Parallel Screening.

Consultative Branch,
Marine Department,
Board of Trade,
Bedford Street, Covent Garden,
London, W.C.,
January 17, 1895.

Sir,

In accordance with your request that I should draw up a memorandum showing the general effect of screening ships' lights in such a manner as to produce, forward of the vessel, a dark parallel lane having a width equal to the distance between the outer edges of the wicks of the lights, I now beg to remark as follows:—

In the Rules for preventing Collisions at Sea it is stated that the coloured side lights of steamers and of sailing vessels must be visible on a dark night with a clear atmosphere at a distance of 2 miles, and show a uniform and unbroken light from right ahead to two points abaft the beam. It is also stated that these lights must be fitted with inboard screens to prevent them from being seen across the bows. There are now no means of knowing the views of those who framed these Rules as to the meaning they attached to the term "right ahead," but as the new system of lighting then introduced was substituted for a system in which there was but one large lamp situated on or near to the bowsprit of the vessel, with a view obviously to its giving a good light ahead, it is, I think, clear that they intended the lights to show ahead of the stem with an intensity at least as great as in any other direction. The term "uniform" in the Rules also shows that they intended the lights to be as clearly visible from ahead as from any other point of the prescribed range, while the condition that they must be visible at a distance of 2 miles proves conclusively that they intended the lights to be good ones.

Moreover, the merest tyro in shipping matters must know that a vessel with lights which either could not be seen, or seen but imperfectly from ahead would be a danger to all other vessels in her proximity.

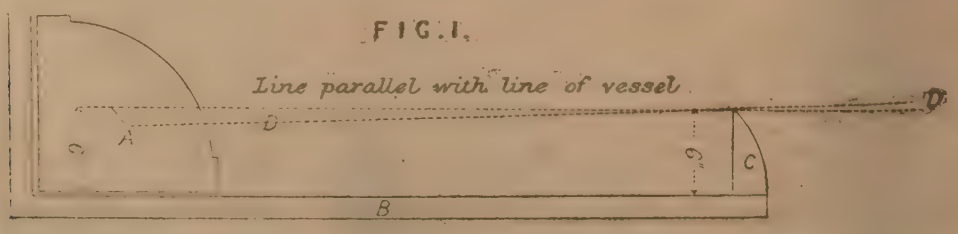
The term "right ahead" in the Rules doubtless means ahead of the stem, not ahead of either light, and if this interpretation be the correct one, the outer rays of the red and green lights must necessarily cross the path of the vessel at some point forward of the stem. This, I may remark, has been the interpretation recognised by the Board of Trade and accepted by the Board's staff since and before I joined the Board's service; and although I am aware that some persons interested in shipping had doubts on the point, I did not know, until the Board's instructions, fixing the angle at which the outer rays of the coloured lights should cross, were issued, that anyone believed it would be dangerous, or even undesirable, to make the lights cross at some point ahead of the vessel.

It, however, now appears from the opposition which has been raised to the present instruction regarding the screening of side lights, that not a few shipowners and others interpret the term "right ahead" to mean ahead of the light, not ahead of the stem, as the Board of Trade have hitherto done. Now, if this interpretation were to be accepted and acted upon, the forward rays of light issuing from the red and the green lamps, which by the present system of screening fall across the vessel's path, would either have to be destroyed by screens or diverted into another direction by the refractive action of some new form of lens, and the result would be a dark parallel lane extending forward of the vessel and having a width equal to the distance between the outer edges of the wicks of the red and green lights. Such lenses are, however, not in existence, and consequently it would be necessary to employ screens. To screen the lights so as to produce the required dark lane (the expression "dark lane" appears to be a product of the Liverpool Steamship Owners' Association) would, however, be impracticable, unless the screens were fitted with chocks; but the latter would have to be of such dimensions as to practically mask the whole of the light when viewed from ahead; and, in consequence of this masking the light would not be of uniform intensity throughout the range prescribed by the Regulations, nor would it be visible at all when viewed from anywhere ahead of the stem. Screens parallel with the middle line of the vessel, but without chocks or other equivalent, would not, even if they were of very great length, keep the forward rays of the lights parallel, and therefore would not fully serve the purpose for which they were intended. The effect of using screens 100 feet in length, of that description, in vessels of different breadths is seen in the following table, the distance from the outer edge of the wick to the outer face of the screen being in each case 6 inches:—

| Distance between the Outer edges of the Wicks of the Lights. | Distance from the Lights to the Point on the Vessel's Path at which the Lights would cross. |
|---|---|
| 20 feet | 2,000 feet = ⅓ mile. |
| 30 „ | 3,000 „ = ½ „ |
| 40 „ | 4,000 „ = ⅔ „ |
| 50 „ | 5,000 „ = ⅚ „ |
| 60 „ | 6,000 „ = 1 „ |
| 70 „ | 7,000 „ = 1⅙ „ |

Figure 1 shows a screen of the regulation length and of the form required to produce a dark lane forward of the vessel, A being the wick of the lamp, B the screen and C the chock. It will be observed, that the distance from the face of the screen to the outer edge of the wick and chock respectively is 6 inches, and that in consequence of this equality the light is completely masked when viewed from ahead.

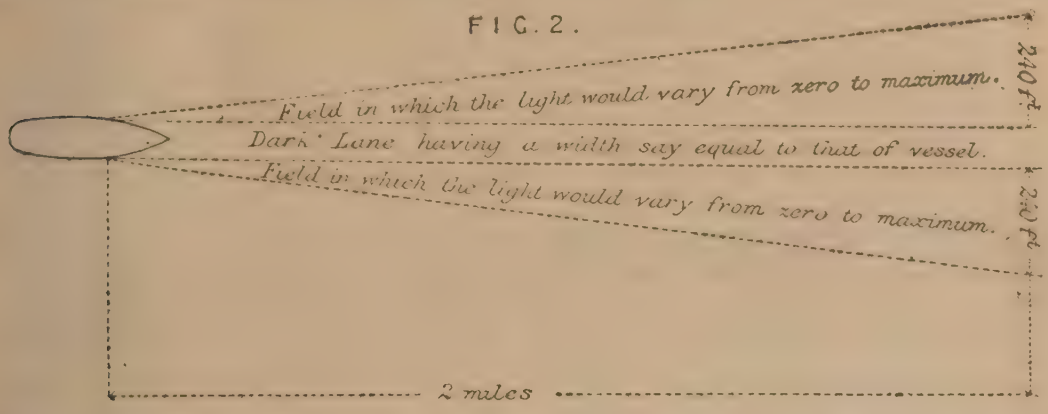
FIG. 1.



If, now, a line DD be drawn from the inner edge of the wick to the outer edge of the chock, the angle formed by it and the line drawn parallel with the middle line of the vessel is the angle through which the light would be of varying intensity. In lamps having wicks 1 inch broad, and placed as in Figure 1, the angle referred to would be about 1° 9′, and the tangent of this angle at a distance of 12,000 feet (2 miles) would be about 240 feet. If, then, the lights were to be screened so as to produce a dark lane forward of the vessel, there would, in addition to the dark lane, be two triangular fields, each not less than 240 feet wide, at a distance of 2 miles from the vessel, in which the brilliancy of the light would vary from zero up to a point approaching the maximum. But lights cannot be screened with absolute precision, and any inaccuracy which might arise from this cause would be just as likely to widen the outer end of the dark lane as to make it narrower.

Figure 2 is a graphic illustration of these conditions, and I think it will require but a moment's consideration to satisfy anyone familiar with the subject that they would not tend to prevent collision at sea, but rather the contrary. An examination of Figure 2

FIG. 2.



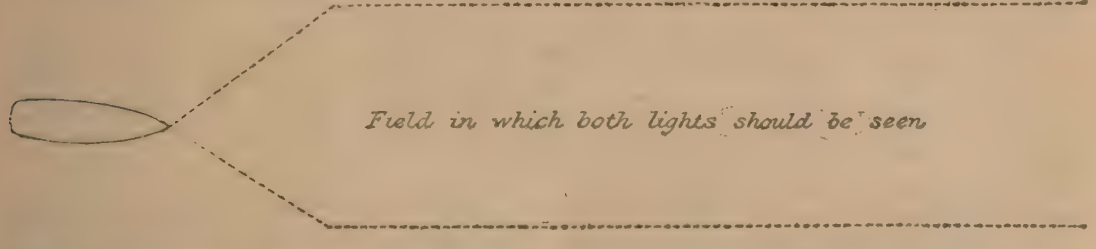
240 ft.
Field in which the light would vary from zero to maximum.
Dark Lane having a width say equal to that of vessel.
Field in which the light would vary from zero to maximum.
240 ft.
2 miles

shows, I think, that those who framed the Rules for Preventing Collisions at Sea, did not use the term "right ahead" to mean ahead of the light, but ahead of the stem, in which case the lights should be arranged to cross at some point ahead of the vessel.

With crossing lights the term "right ahead" is, however, somewhat indefinite, in consequence of the distance from the stem to the crossing point not being stated; but those who framed the rules doubtless intended it to be a reasonable one, for the distance at which the lights of vessels can be seen changes with the condition of the atmosphere as well as from other obvious causes, and it is when the conditions are least favourable in this respect that collisions are likely to occur.

Now, if it be conceded that the lights should cross, the crossing angle chosen by the Board of Trade, viz., 4°, is, I think, the best that could be selected. If the angle were less the width of the field in which both lights are seen would not be sufficient at what may be termed the critical distance, *i.e.*, from a quarter to half a mile from the vessel, and if it were greater the width of the field at a distance, say, of 2 miles from the vessel would be unnecessarily great.

The ideal field in which both lights should be seen is of a rectangular form, thus—



its width being, say, six times that of the vessel, but a field of that form cannot be produced, and to get the necessary width near the vessel in a field of a triangular form the base of the triangle (width of the field at a distance of 2 miles) must be greater than is necessary.

The following table, which is almost identical with one prepared by yourself, shows clearly that when the lights are screened to 4° the width of the field in which both lights are visible is at the critical distance somewhat less than it should be, but, as previously pointed out, this cannot be obviated if the width of the field at the 2 miles distance is to be kept within reasonable limits.

Ships meeting and distant 500 Yards (¼ Mile) from each other, and bearing from the intersection of the extreme outer rays of their side lights 4° and 3°.

App. 2, No. 14.

Ships meeting and distant 1,000 Yards (½ Mile) from each other, and bearing from the intersection of the extreme outer rays of their side lights 4° and 3°.

| 4° on each other's Bow. | | | 3° on each other's Bow. | | |
|---|---|---|---|---|---|
| Transverse Distance between the outer Edges of the Wicks of the two Lights of each Ship. | Distance between the Paths of the two Ships or Half Breadth of the Field. | Distance they will pass clear of one another, after allowing for their Half Breadths. | Transverse Distance between the outer Edges of the Wicks of the two Lights of each Ship. | Distance between the Paths of the two Ships or Half Breadth of the Field. | Distance they will pass clear of one another, after allowing for their Half Breadths. |
| Feet. | Feet. | Feet. | Feet. | Feet. | Feet. |
| 30 | 195 | 165 | 30 | 142 | 112 |
| 40 | 190 | 150 | 40 | 137 | 97 |
| 50 | 185 | 135 | 50 | 132 | 82 |
| 60 | 180 | 120 | 60 | 127 | 67 |
| 70 | 175 | 105 | 70 | 122 | 52 |

In the above it is assumed that both ships keep their course. The figures given are the nearest whole numbers.

The width of the field at a distance of 2 miles is, in the case of a vessel with lights 70 feet apart, 536 yards; consequently its extension on each side of the vessel's path is half that amount, or 268 yards, which is fully 11 beams of the vessel.

I should here mention, however, that it is only on dark nights with a clear atmosphere that coloured side-lights can be seen at a distance of 2 miles, and then the lights are so feeble that it is exceedingly difficult to locate them without the aid of a field glass. Indeed, even with such aid it is by no means an easy matter to find them unless one knows the direction in which the vessel to which they belong is approaching. In view of this fact it is, I think, very improbable that the courses of two steamers meeting, and seeing each other's red and green lights, would be altered by porting their helms when so far apart; it is far more probable that they would approach until the opposing lights were fairly distinct, for, apart from the indistinctness of the lights, the rule requiring two steamers meeting to port their helms is only to be applied when their position involves risk of collision. The records of the Admiralty Courts would, I think, prove that such has been and is now the practice.

The width of the triangular field at a distance of 2 miles from the vessel is, therefore, I think, of little moment, except that it is a measure of its width at lesser distances, say a mile downwards, and it will be seen from the following table that when lights are screened to 4°, the widths at these lesser distances are but moderate:—

| Distance between the outside Edges of the Wicks of the Lights. | Distance from the Lights to the Crossing Point. | Distance from the Lights to the Points in the Field where the Breadth is measured. | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | | ⅛ Mile. | | ¼ Mile. | | ½ Mile. | | ¾ Mile. | | 1 Mile. | |
| | | Half Breadth of Field. | Breadth of Field. | Half Breadth of Field. | Breadth of Field. | Half Breadth of Field. | Breadth of Field. | Half Breadth of Field. | Breadth of Field. | Half Breadth of Field. | Breadth of Field. |
| Feet. | Feet. | Feet. | Feet. | Feet. | Feet. | Feet. | Feet. | Feet. | Feet. | Feet. | Feet. |
| 30 | 215 | 37 | 74 | 90 | 180 | 195 | 390 | 300 | 600 | 405 | 810 |
| 40 | 286 | 32 | 64 | 85 | 170 | 190 | 380 | 295 | 590 | 400 | 800 |
| 50 | 358 | 27 | 54 | 80 | 160 | 185 | 370 | 290 | 580 | 395 | 790 |
| 60 | 429 | 22 | 44 | 75 | 150 | 180 | 360 | 285 | 570 | 390 | 780 |
| 70 | 501 | 17 | 34 | 70 | 140 | 175 | 350 | 280 | 560 | 385 | 770 |

At the higher limit (1 mile), the breadth varies from 770 feet, in the case of a very large vessel, to 810 feet in the case of a small one, the half breadths being 385 and 405 feet respectively, while, at a distance of a quarter of a mile from the lights, the breadth varies from 140 feet in the case of the large vessel to 180 feet in the case of a small one, the half breadth at this distance being only 70 and 90 feet respectively. I may state in this connexion, that the majority of the members of the Maritime Conference at Washington agreed that the coloured side lights should cross ahead of the vessel, and although they did not go so far as to recommend the screening of these lights to a fixed angle, they indicated clearly what their thoughts were on the subject, by passing a resolution admitting of their being screened to an angle not exceeding half a point (5⅝°), which is a greater angle by 1⅛° than that allowed by the Board's printed instructions.

With regard to the opposition from outside to the present system of screening lights, I believe it has arisen solely owing to those taking part in it not being familiar with the manner in which lights have been screened in the past; to a certain indefiniteness in the phraseology of the Regulations for Preventing Collisions at Sea; to a mistaken belief that coloured side lights are distinctly visible at a distance of 2 miles; to their inability, owing to want of the necessary practice, to appreciate the difficulty that would be experienced in screening lights so as to produce a dark lane, and also the dangers that would arise if that system of screening were adopted, even if great accuracy of screening could be attained.

I may add, in conclusion, that the effect of the Board's present instructions regarding coloured side lights has been to make certain what was uncertain and indefinite; to promote uniformity of practice amongst the surveyors as well as amongst those whose duty it is to screen the lights on behalf of shipbuilders and others; to increase the efficiency of the lights, and, further, to reduce the angle of screening, and thereby to lessen the width of the field in which both lights are visible ahead of the vessel.

Moreover, throughout the 22 years I have had the honour and pleasure of serving the Board of Trade, I do not know of anything having been done by the Marine Department more calculated to reduce loss of life at sea, than the alterations which were made in the instructions regarding ships' side lights, at the time the angle of screening was fixed; I do not, however, wish it to be inferred from this that I consider the present instructions and mode of dealing with ships' lights perfect; on the contrary, I think much remains to be done, but a great improvement has undoubtedly been effected, and I know that this opinion is shared by a great many of those of the Board's staff who have had to deal with lights under the new and old instructions.

I am, Sir,
Your obedient Servant,
Peter Samson.

Sir Digby Murray, Bart.,
Marine Department, Board of Trade.

Note.—The numbers given in this Table are the nearest whole numbers. The minus sign before a number signifies that the most convergent rays do not cross the middle line. The figures given in the two columns (except the first) are not two actual distances but those found on the two most convergent rays as two long lines, each cutting the *outer* edges of the screens and wicks of the respective lights. For [illegible] of scales, *see* Appendix.

App. 3, No. 2.

No. 2.—Tables showing (1) the Distance from the Lights to the Points ahead of the Vessel where the most Convergent Rays, issuing from the Inner Edges of the Wicks, cross; and (2) the Distance from these Rays to the Middle Line of the Vessel extended forward (vessel's path).

Outer Edge of Wick Screened to 1°.

| Width or Equivalent Width of Wick. | Distance between the Outer Edges of the Wicks of the Lights. | Distance from the Lights to the point where the most Convergent Rays, issuing from the Inner Edges of the Wicks, Cross. | Distance from the Lights to the Points in the Middle Line referred to above. | | | | | |

# APPENDIX No. 5.

*Papers handed in by the Chairman.*

App. 5, No. 1.

## No. 1.—Letter from the Principal Officer of the Board of Trade at Cardiff as to the Angle of Screening on Foreign Ships.

*Screening of Side Lights of Foreign Vessels.*

Board of Trade, Surveyor's Office,
Cardiff, 16th May 1895.

Dear Mr. Hipwood,

In response to your note of the 7th inst. on this subject, I now beg to forward you a list of foreign vessels I have had visited in this district between the 8th and 15th of May. The vessels were visited as they came in the way of the surveyors' several rounds, and they are the results of the inspection of seven different surveyors. The summary comes out thus:—

*Total Vessels.*

The total number of vessels visited was 50, of which 38 are fitted with side light screens arranged to project the light ahead at an angle of 4° and over, while 10 are screened to a finer angle than 4°, and two to an angle of 5½° outward.

*Steamers.*

Of the 50 vessels, 17 are steamers, divided as follows:—2 Swedish, 1 Norwegian, 6 French, 4 German 1 Belgian, 2 Austrian, and 1 Greek. 12 of these are screened to 4° and over, while 4 are at 3°, and 1 at less, viz., 1° 28′.

*Sailing Vessels.*

Of the 33 sailing vessels, 2 are Swedish, 14 Norwegian, 1 Spanish, 10 French, 2 Germans, 1 Dutch, 1 American, 1 Danish, and 1 Italian.

Of these 26 are screened to 4° and over, 2 to 3°, 1 to 2°, and 2 to under 2°, while 2 are screened to an angle of 5½° outwards.

This is a fair sample of what we are meeting in every-day practice.

Yours faithfully,
Alfred J. G. Chalmers.

C. Hipwood, Esq.,
Secretary,
Side Light Screening Committee,
Marine Department.

Foreign Vessels inspected in South Wales District for Screening of Side Lights between 8th and 15th May 1895.

| Name of Vessel (Steam or Sailing). | Nationality. | Details of Screening. | Angle. |
|---|---|---|---|
| Henriette (sailing) | Norwegian | Carried on stanchions abaft fore-rigging in fine, and on aft end of poop rail in foul, weather. | 7° 17′ and 7° 36′ port, 6° 48′ and 7° 8′ starboard (two sets of lanthorns). |
| Drott (steam) | Swedish | Carried on cranked stanchions above pilot bridge rail amidships. | 3° 13′ port, 4° 15′ starboard. |
| Minna (steam) | German | Carried on outer ends of pilot bridge platform amidships. Certificates of inspection dated December 1891 on board (German). | 4° 10′ port, 4° 10′ starboard. |
| Amiral Cecille (steam) | French | Carried on crank stanchions above pilot bridge amidships. | 2° 45′ port, 3° 23′ starboard. |
| Herman (sailing) | Norwegian | On davits, fore-rigging, port inclined inwards 2″ in 3′, starboard inclined outwards 3″ in 3′. | 5° port inward, 3° starboard outward. |
| Skiblander (sailing) | Norwegian | Abaft fore-rigging on straight stanchions, each screen inclined inwards 2″ in 3′. | 9° inwards. |
| Princesa Dagmar (sailing) | Spanish | Mizen rigging on straight stanchion, each screen inclined outwards 5½″ in 4′. | 5½° outwards. |
| Rosa (sailing) | French | Fitted on the quarters on single davits | 5½° outwards. |
| Arestos (sailing) | Norwegian | Fore side. Fore-rigging on straight stanchions. | 8° inwards. |
| Statsminster Stang (sailing) | Norwegian | Fore side. Fore-rigging on straight stanchions. | 8° inwards. |
| Union (sailing) | French | On each quarter on single davit | 6° inwards. |
| Gyda (steam) | Norwegian | Screens 3′ 9″ | 3¾° port, 3¾° starboard. |
| Stella (steam) | Swedish | Screens 3′ 6″ | 4½° port, 4¾° starboard. |
| Atlantic (sailing) | German | Screens 3′ 9″ | 4° full port, 4° bare starboard. |
| Otto (sailing) | German | Screens 4′ 0″ | 5¾° port, 5° starboard. |
| Gaudal (sailing) | Norwegian | Screens 3′ 8″ | 5½° port, 4½° starboard. |
| Louise Eugene (sailing) | French | Screens 2′ 1″ | 1° stanchion port bent, 9° starboard. |
| Anna (sailing) | French | Main rigging on stanchions | 11° inwards. |
| Leonidas (sailing) | French | Main rigging on stanchions | 9° inwards. |
| G. G. M. (sailing) | French | Carried right aft, on single davits | 9° inwards. |
| Urie (sailing) | French | Carried right aft, on single davits | 6° inwards. |
| Hoogeland (sailing) | Dutch | Carried in main rigging, seized to shrouds | 11° inwards. |
| Ellen (sailing) | Swedish | Carried right aft, on davits | 3° inwards. |
| Erbrin (sailing) | Norwegian | Fore side of fore-rigging | 5° inwards. |

App. 5, Nos. 1 and 2.

| Name of Vessel (Steam or Sailing). | Nationality. | Details of Screening. | Angle. |
|---|---|---|---|
| Benjn. F. Packard (sailing) | United States | Screens parallel to keel, cleat 41 inches before the wick. Lamps carried in towers at after part of forecastle. | 4° 32′ inwards. |
| Marie Celine (sailing) | French | Screens attached to the main rigging. Screens not parallel, and only 33″ before wick. No cleats. | 6° 6′ inwards. |
| Leonie Anastaise (sailing) | French | Screens are on bowed-out stanchions, secured with an iron stay abreast the main rigging. They are parallel. Screens 39 inches before wick. | Starboard 4° 25′, Port 5° 9′. |
| Estelle Leon (sailing | French | Screens are lashed to the fore-rigging, not parallel; they are 4½ inches more apart at the after end than the fore end; no cleats. Screens 50 inches before wick. | 8° 38′. |
| Albis (steam) | German | Screens not parallel; 3½ inches broader apart at fore end than after end. Cleats 3 inches on at 39 inches before wick. | 1° 28′. |
| Esmeralda (sailing) | Norwegian | Screens on stanchions abreast the fore-rigging. Parallel to keel no cleats, Screens 44 inches before wick. | 5° 52′. |
| Daggrif (sailing) | Norwegian | Screens on stanchions abreast the main-rigging not parallel to keel. 3½ inches broader at fore end than the after end. Cleats 2½ inches on at 35 inches before wick. | 1° 14′. |
| Emma (sailing) | Norwegian | Screens on a single bowed-out stanchion just before the mizen-rigging secured in place with rope lashings, not parallel. Screen 36 inches before wick. | Nearly 2°. |
| Dagmar (sailing) | Danish | Screens carried on stanchions right-aft on the quarters, not parallel. Screens 61 inches before wick. | 0° 56′. |
| Primus (sailing) | Swedish | Screens carried on bowed-out stanchions abreast main-rigging, not parallel. No cleat on starboard screen; starboard screen 42 inches, port 39 inches; screens secured in place with rope lashing to rigging. | Starboard 4° 47′, Port 0° 44′. |
| Besratael (steam) | Belgian | Screens placed on bridge deck on swing-out stanchions. | 4°. |
| Colonist (sailing) | Norwegian | Screens outside fore-rigging on stanchions | 2½°. |
| La Rochelle (steam) | French | Screens placed on upper bridge on swing-out stanchions. | 4°. |
| Commentry (steam) | French | Screens placed on upper bridge on swing-out stanchions. | 4°. |
| Valin (steam) | French | Screens on upper bridge on swing-out stanchions. | 3°. |
| Neapel (steam) | German | Screens chocked to 4° angle but being not fore-and-aft, but pointing out the actual screening is. | Port 3°, Starboard 2°. |
| Listo (sailing) | Norwegian | Carried foreside of fore-rigging | 6°. |
| Eliser (sailing) | Norwegian | Carried foreside of fore-rigging | 4°. |
| Venezulla (sailing) | Norwegian | Carried foreside of fore-rigging | 6°. |
| Boucau (steam) | French | Screens on upper bridge on swing-out stanchions. | 4°. |
| F. Bischoff (steam) | German | - | 4°. |
| Burma (steam) | Austro-Hungarian | - | 3°. |
| Francisco Gotuzzo (sailing) | Italian | Screens if fore-and-aft would be to 4° angle, but both point inboard. | 6°. |
| Bearn (steam) | French | Screens on upper bridge on swing-out stanchions. | 4°. |
| Ulysses (steam) | Greek | Screens on upper bridge on swing-out stanchions. | 4°. |
| Szant Laszlo (steam) | Austro-Hungarian | Screens on upper bridge on swing-out stanchions. | 5°. |

May 16, 1895.

ALFRED J. G. CHALMERS.
Principal Officer, South Wales District.

No. 2.—LETTER from the PRINCIPAL OFFICER of the BOARD of TRADE at NORTH SHIELDS as to the ANGLE of SCREENING on FOREIGN SHIPS.

*Screening of Side Lights of Foreign Vessels.*

Board of Trade Surveyor's Office,
North Shields,
14th May 1895.

SIR,

As requested by Mr. Hipwood I send some particulars of the screening of the side lights of 20 foreign vessels examined on the Tyne between the 8th and 13th instant.

It will be seen that the average angle of convergence is greater than that required by the Board's regulations for British ships.

If you approve please hand the lists to Mr. Hipwood for the information of the Committee

I am, &c.,
JAMES RAMSAY.

Sir Digby Murray, Bart.,
Board of Trade.

Further particulars can be obtained if necessary.

App. 5, Nos. 2 and 3.

*Screening of the Side Lights of some Foreign Vessels, examined on the Tyne between the 8th and 13th May* 1895.

Board of Trade Surveyor's Office,
North Shields.

Sir, 14th May 1895.

In accordance with your instructions I have examined the side lights of some 20 foreign vessels on this river. The vessels were not selected in any way, but were taken haphazard. The results are given on the two sheets attached

The average angle of screening, as found by drawing a line from the outer edge of the wick to the end of the screen or chock, and intersecting a fore and aft line through the latter point, is, in the case of eight sailing vessels, omitting the one where the wicks were obscured right ahead, a little over 6°; and in the case of the 11 steamers is a little over 5°.

I am, &c.,
Arthur Jackson,
Surveyor.

The Principal Officer,
N. Shields.

Screening of the Side Lights of some Foreign Steamers examined on the Tyne between the 8th and 13th May 1895.

No. 3.—Official Report of the Inquiry into the Collision between the "Brinkburn" and the "Alvah."

*See* Question 1189.

(No. 5142.)

"BRINKBURN" (S.S.)

AND

"ALVAH" (S.S.)

10th April 1895.

George Jacob, master of the British S.S. "Brinkburn."

The Court, in the matter of a formal investigation held at Valletta, Malta, by me, the undersigned Magistrate of Judicial Police, on the nature and cause of the collision which took place in the Straits of Messina on the 29th March last, at about 8.30 p.m., between the British S.S. "Brinkburn" and the British S.S. "Alvah." I appointed as nautical assessors to assist me, the master mariners Salvatore Stivala and Rosario Frendo Azopardi, and on the 5th inst. I opened the investigation by taking, in the first place, the unsworn evidence of George Jacob, the master of the "Brinkburn," duly warned by me, and then those of Francis

Reval, an engineer and naval constructor, a passenger on board the "Brinkburn," as representing the French Government; of Antione Tracon, a first lieutenant in the French navy, another passenger; of Lewis William, the man at the wheel on the "Brinkburn" at the time of the collision; of Samuel Shelduck, chief engineer; of Joseph Dauphin, the man on the look-out; George Alcock, supernumerary second mate, and John Trickey, all belonging to the "Brinkburn."

From the evidence taken it appears that the "Brinkburn" is a British S.S., bearing the official number 102,849, built of steel one year ago in Stockton, registered in the port of London, of the registered tonnage 2,096, owned by Messrs. Harris and Dixon, of London. On the 5th March last the ship left Havre for Toulon, laden with French Government stores, and on the 27th March left Toulon with a fresh cargo of French Government stores, bound to Madagascar. On the 29th March last, at about 8 p.m., the ship doubled Cape Faro, in the Straits of Messina, at a distance of about half a mile from the land, the master being at the time on the bridge. The night was clear and the sea smooth, the "Brinkburn" then going at full speed. In steaming through the Straits the master perceived a steamer's bright and green lights on his starboard bow, and kept his course; but when drawing near the other steamer, the "Brinkburn" was caught by an eddy current and ran against her starboard helm until her head was brought almost at a line with the other ship. Immediately after the red light of the other steamer was visible, and the "Brinkburn" suddenly flew off to port. The master of the "Brinkburn" then blew two blasts of the whistle to indicate that his vessel was swinging to port, and reversed engines to full speed astern. No answer was given to his blasts, and he immediately blew out two other blasts, which were only answered by one the engines still going full speed astern. This notwithstanding, the collision became unavoidable, and the other steamer was struck on her port side almost amidships. The "Brinkburn" had part of her stem carried away, with several iron plates. The other steamer, which a few hours afterwards foundered on the Calabrian coast, proved to be the British S.S. "Alvah," of Aberdeen, coming from the Black Sea with a cargo of wheat for Antwerp.

Immediately after the collision the master of the "Brinkburn" ordered three boats to be lowered to give assistance to the "Alvah"; the crew of the last ship were found already in their boats, but being overcrowded, the boats of the "Brinkburn" picked up seven men in one of their boats and took them on their ship. The "Brinkburn" then entered the port of Messina and landed the men of the "Alvah."

In the opinion of the assessors, which I find no reason to disapprove, it appears that the "Alvah" ought to have kept the Calabrian coast of the Straits in going through it from its southern part, and as the weather was fine and the sea smooth, nothing could have excused her for keeping so close to the Sicilian coast.

The absence of any of the crew of the "Alvah" prevented me from hearing any evidence on that side, and consequently I had to satisfy myself of the evidence only of a part of the crew of the "Brinkburn."

Master Jacob, when being caught by the eddy current, in the opinion of the assessors, which I confirm, did all he could to avoid the collision, but on doubling the Faro Point he did not give a wider berth, which might probably have caused him to avoid the whirlpools which generally exist near Faro Point; the whirlpools being the motive that his ship did not answer her helm.

The Court therefore disapproves the course followed by Master George Jacob in passing through narrow waters, where whirlpools are known to be of frequent occurrence, in so close a proximity to the land as half a mile, the collision being due only to the strength of the eddy currents, and might have thus been avoided. I find, however, no reason to interfere with the master's certificate of competency, dated 27th August 1878, No. 21,328, which is consequently delivered back to him, and feel myself only bound to caution him for the future.

At the last stage of the inquiry, Notary George Alfred Page appeared on behalf of the "Alvah," empowered by telegram. App. 5, No. 3.

(Signed) P. Frendo Azopardi, Magistrate.

We concur.

(Signed) S. Stivala, R. Frendo Azopardi, } Assessors.

*Opinion of Assessors.*

We the undersigned master mariners, appointed nautical assessors for the purpose of assisting the magistrate, Mr. P. Frendo Azopardi, in the investigation as to the cause of collision between the British S.S. "Brinkburn" and the S.S. "Alvah," of Aberdeen, after careful examination of witnesses, report as follows:—

The British S.S. "Brinkburn" left Toulon on the 27th March 1895, laden with French Government stores for Madagascar, under the command of Captain G. Jacob.

On the evening of the 29th, at about 8 o'clock, she was rounding the Faro Point at a distance of about half a mile from land, Captain G. Jacob being at the time on the bridge. The night was clear and the sea smooth. The ship was then going at a full speed. On rounding the point a masthead light and a green light was sighted on the starboard bow. The "Brinkburn" proceeded on her way, but a few minutes afterwards she was caught by an eddy current. The helm at the time was hard-a-starboard, but the ship swung against her helm until her head was brought almost in a line with the other ship. Immediately after the red light of the other ship was seen, and the "Brinkburn" suddenly flew off to port. Captain Jacob, seeing the dangerous position of the ship, blew two blasts of the whistle to indicate that the vessel was swinging to port, and reversed engines to full speed astern; but as the other steamer did not give any answer to the whistle, he gave two more blasts, which were answered immediately by one. The engines were still going full speed astern, but this did not prevent the collision; and the other steamer, which was struck on her port side nearly amidships, and a few hours afterwards foundered on the Calabrian coast, proved to be the S.S. "Alvah," of Aberdeen, coming from the Black Sea laden with grain for Antwerp. The "Brinkburn," immediately after the collision, sent three boats in assistance of the other ship, and found the crew already in their own boats; but, being overcrowded, they removed seven individuals and took them on board, who subsequently were landed at Messina.

The "Brinkburn" had carried away part of the stem and several iron plates from the 20 ft. mark down to the fore foot of the ship, and came to Malta for repairs. The evidence heard in this inquiry was only limited to the crew and passengers of the "Brinkburn," as the crew of the "Alvah" were not available at Malta.

It appears that the "Alvah," ought to have kept the Calabrian side of the Straits in going through it from its southern part, and nothing in the state of the weather justified her keeping so close to the Sicilian coast.

The master of the "Brinkburn," when caught by the eddy current, did all what a seaman could possibly do to avoid the collision; but we are of opinion in doubling the Faro Point he did not give it a wider berth. By so doing he could have probably avoided the whirlpools that generally exist near Faro Point, which prevented his ship from answering her helm.

(Signed) S. Stivala, R. Frendo Azopardi, } Master Mariners.

Valletta, Malta, 10th April 1895.

Confirmed on oath by the assessors, 10th April 1895.

(Signed) F. S. Rossignaud, Clerk.

P. Frendo Azopardi, Magistrate.

Issued in London by the Board of Trade on the 13th day of May 1895.

# APPENDIX No. 6.

*Papers handed in by Mr. Anderson.*

App. 6, No. 1. No. 1.—Paper on the Screening and Position of Ships' Side Lights, read before the Chamber of Shipping of the United Kingdom at the Annual Meeting, 1st February 1893, by J. G. S. Anderson, Esq.

## Ships' Side Lights.

New instructions by Board of Trade to their surveyors (1892).

Early last year a circular containing new instructions on the subject of side lights was issued by the Board of Trade to their surveyors.

Legality and expediency of instructions.

These instructions involve a change in the method of screening which I believe to be both inexpedient and illegal—inexpedient, because it will do much to impair the value of side lights as an indication of the course steered; illegal, because the change in the screening does not bear the sanction of a new Order in Council, and is in conflict with the conditions which the last Order* on the subject appears to lay down.

Conditions laid down by last Order in Council.

The conditions I specially refer to are three, viz.:—

(1.) That the side lights shall be so constructed as to show an uniform light over an arc of the horizon of 10 points.

(2.) That they shall be so fixed as to throw the light from right ahead to two points abaft the beam.

(3.) That they shall be so fitted with inboard screens as to prevent their being seen across the bow.

New departure in method of screening.

The new instructions prescribe that in future the lights shall be screened, so that their rays converge ahead of the stem, each light at an angle of 4° to a line parallel with the keel.

At variance with Act of Parliament.

If so screened, the lights will violate all three of the above-named conditions.

(1.) They will each show a light over an arc of the horizon not of 10 points, but of 10 points plus 4°.

(2.) They will not throw the light from right ahead to two points abaft the beam, but from a point on the opposite bow.

(3.) They will be seen across the bow.

Legal opinion as to its legality.

Quite apart from the merits of the change, I am advised that it is illegal, and that such a departure from the principle sanctioned by English and International Maritime Law will, in the event of collision, put out of court any ship which has adopted it, if any question of lights is involved in the merits of the collision.

Board of Trade view as to its legality.

I have, by the courtesy of Sir Digby Murray, had an opportunity of obtaining an explanation of the objects of the Board of Trade in making the change, and of their authority for doing so. That any extraordinary authority is required they deny; their view, as I understand it, being that there is practically no change involved; that the last Order in Council, if read broadly, is not in conflict with the new instructions; that the practice, in the great majority of cases, has been in the past to screen the lights at an angle of greater or less convergence (say on an average 4° each light); and that the purpose of the new instructions is merely to recognise the existing practice, and to bring about uniformity in the angle to which the side lights shall converge.

The words of the Order "right ahead" when read with the restriction of the arc to 10 points of the compass, measured from two points abaft the beam, cannot, I believe, bear any meaning other than that each light is to be visible right ahead at any point along an imaginary line drawn parallel with the keel in prolongation of the screen.

To the objection that any convergence whatsoever must therefore contravene the statutory rule, the Board of Trade reply that they construe the words "right ahead" as meaning right ahead of the ship, that is to say, that both lights must be visible along an imaginary line drawn in prolongation of the line of the ship's keel, and that this cannot be effected without angling the lights.

To the objection that the Order forbids the lights being screened across the bow, they reply that the words "seen across the bow" mean seen across the bows of the ship; consequently that provided the green and red rays do not cross abaft the stem of the ship, there is no limitation imposed on the angle of convergence.

The instructions inconsistent with Board of Trade interpretation of Order in Council.

If we accept these interpretations as correct, if the Order does indeed contemplate both lights being visible at any point along an imaginary continuation of the keel line, and permits of their being screened at the angle of convergence necessary to effect this, then the limitation of the angle of convergence to 4°, which would make the two side lights visible along this imaginary line only at distances varying with the width of the ship, is inconsistent with the Board's own construction of the words "right ahead."

The Board of Trade hold that the condition that the light shall be uniform over an arc of 10 points means that it shall be of uniform brilliancy over that arc, and that it is impossible to secure this without allowing the ex-focal rays to cross the bow.

I cannot say whether or no this alleged impossibility has ever been demonstrated, but in any case the Order limits the arc to 10 points, and forbids the showing of the light across the bow.

Result of an examination of existing side lights by Board of Trade surveyors.

To prove that the practice of angling lights is no innovation, Sir Digby Murray has shown me particulars of a recent examination by Board of Trade surveyors of the side lights of a number of vessels in London and Liverpool. These disclose variations in the screening of side lights ranging from 14° convergence to an angle of 4° divergence in each light, while in many cases the starboard and port lights were screened to different angles, the starboard light in one example being screened inwards to an angle of 5°, and the port light outwards to an angle of 4°. A passenger ship is mentioned, both of whose lights could be seen at once from a point 20 ft. abaft the stem.

On the other hand, in the case of one "large line of passenger steamships," as well as in isolated instances, the side lights were reported as being screened parallel to the keel.

Whether, however, it is proved on inspection that the practice of angling side lights has prevailed in the past or not does not really affect the question. That the law had been broken by many in the past, would not be a good reason why in the future it should be broken by all.

Proved lack of attention to side lights hitherto.

One thing the figures I have quoted certainly show. That it is high time attention should be directed to the subject of side lights, with a view to bringing about precision and uniformity in practice with regard to them. Uniformity in itself, however, is not a virtue, and until the law is altered the practice should, I think, be uniformly in accordance with what I take to be the meaning of the rules sanctioned by the Order in Council, and not with what I venture to call the strained intrepretation which the Board of Trade put upon it in order to extract from the law a sanction for the change.

So much for the question of legality.

Expediency of Board of Trade interpretation.

Now for the question of the relative expediency of the two interpretations.

Diagram No. 1.—Parallel screening.

No. 1* is an enlargement of a diagram prepared by the Board of Trade to illustrate the one objection which they have raised to what I may distinguish as parallel screening, viz., that as light travels in straight lines, there must be what they call a dark lane, varying with the width of the ship, within which neither side light would be visible however great the distance from them. They do not speak of the mast-head light.

*Notes by Sir Digby Murray on Diagram* 1.

"It does not matter what the breadth, or the relative "breadth, of the steamships may be, if the lights are "screened as shown it is a mathematical impossibility "for an observer in any position whatever to see both "the side lights at one and the same time.

"A and B are two steamships meeting end on. The "officer of the watch on board of A cannot see the side "lights of B, no matter on what part of the bridge he is

* The latest Order of Council dealing *inter alia* with this subject was made under the Merchant Shipping Act Amendment Act of 1862, and is dated 11th August 1884.

Wyman & Sons, Ltd. Lith 7160. 5. 95

"standing, nor is it possible for the officer of the watch "on board A to see both side lights of B at the same "time, no matter how the position of A with reference "to B may be varied.

"The officer of the watch on board of B if he stands in "the middle of the bridge cannot see either of the side "lights of A.

"If he stands on the extreme starboard side of the "bridge he sees the red-light only, and if he stands on "the extreme port side of the bridge he sees the green "light only, nor can the position of B be varied so as to "enable him to see both the side lights of A at one and "the same time.

"To remedy this state of things, the side lights must "cross at some angle ahead of the ship—Art. 3 (*b*) and (*c*) "say, 'so fixed as to throw the light from right ahead "to two points abaft the beam,' and the Board of Trade "have always construed 'right abead' to mean right "ahead of the ship.

"The Washington Conference say—'The side lights "'should be so screened as to prevent the most conver-"'gent rays of the light being seen across the bows more "'than half a point.' The Board of Trade, after careful "experiments, have fixed this angle at 4° measured "from the outer edge of the wick. If the wick is 1¼ ins. "in width, the angle will be about 3° if measured from "the centre, and 2° if measured from the inside edge "of the wick."

The "dark lane" difficulty.

It is, no doubt, mathematically true that there would be such a dark lane, but I have not been able to obtain evidence that any navigator ever noticed it, still less that any collision has ever been traced to that cause. And for this reason, no doubt; that the course of a ship under way is not mathematically straight. If we could conceive of two ships approaching each other on parallel lines of rail, one set within the other, on something like broad and narrow gauges, the dark lane might but for the mast-head light be a real danger. The sight of that light would let the navigator know that there was something there, and it would be his duty to keep clear. But, in fact, I believe it is fine steering under the most favourable conditions of sea and wind to keep a ship steady within 2° of a straight course. It follows that the dark lane is always being thrown about just as a bright lane is thrown about by a projector. It "cannot rest."

Assuming, therefore (and it is a considerable assumption), that two ships should approach one another dead end on, an almost imperceptible yaw would suffice to make one or other of the side lights visible. The greater the distance the ships are apart the larger the arc through which the dark lane is perpetually travelling and with it the rays of the side lights, and the more minute the angle of deviation required. To take the case of our diagram, the arc over which the dark lane has to travel in order to render the side lights of B visible to A would be some 10 to 15 feet either way. The yaw required to effect this, assuming the required arc to be 15 feet, would be:—

At a distance of 2 nautical miles, 4·2 minutes, or say $\frac{1}{15}$ of a degree.

At a distance of 1 nautical mile, 8·4 minutes, or say $\frac{1}{7}$ of a degree.

At a distance of ½ nautical mile, 16·9 minutes, or say $\frac{2}{7}$ of a degree.

At a distance of ¼ nautical mile, 33·8 minutes, or say $\frac{4}{7}$ of a degree.

I have not made the calculation for a distance of less than a quarter of a mile, because even slow steamers approach each other at a speed which would bring them together in from 40 to 60 seconds after first seeing each other at a quarter of a mile distance, and at shorter distances than this there would not, as a rule, be time for the ships to go clear.

The Board of Trade, on this diagram, assume, in order to strengthen their argument, an officer stationary on one spot in the centre of B's bridge. But the Order in Council does not speak of a particular officer in a particular position. It speaks broadly of the *ship* as "seeing." It assumes that a good look-out is kept, and that being granted, even if A failed to see B's side lights, an officer at either end of B's bridge will see A's, whereupon B would at once alter her course, and by so doing, disclose one of her side lights to A. The mast-head lights of both vessels would, as I have said, be all the time visible to each other.

Diagram No. 2.—Convergent screening.

Having dealt with the objection to parallel screening, I turn to the scheme for convergent screening, advocated by the Board of Trade, the object of which is to obviate what, as I have indicated, I think is a merely imaginary danger. This diagram, No. 2,* is intended to illustrate the practical bearing of such screening. It will be obvious that, to any ship approaching another ship with side lights thus converging, the latter will appear within a certain triangle, no matter what course she is steering, to be coming end on to the former, that is to say, within the area where both lights are visible, the lights will give no indication of the course being steered. It will thus, under the present rule of the road, be frequently the duty of two ships approaching one another to cross each other's bows, when, by holding on their respective courses, they would have gone clear. They will therefore be running unnecessarily into danger, which, in waters where a succession of vessels may be encountered, will be constantly recurrent; the danger being at the same time aggravated when so manœuvring in narrow channels. Diagram No. 3† is intended to illustrate this.

App. C, No. 1.

Diagram No. 3.—Convergent screening specially dangerous in narrow channels.

Under similar circumstances, parallel screening would show whether or not the vessels might safely hold on their courses.

Summary.

I have now indicated my opinion, for what it may be worth, that the change, until sanctioned by an Order in Council, is illegal, and that the only objection to parallel screening is, from the practical point of view, a fanciful one, whereas convergent screening greatly impairs the value of the side lights as a means of notifying the course steered, and thereby gives rise to new dangers and inconveniences.

Protest of Trinity House Pilots.

I can give no better evidence of the verdict of practical men upon the Board of Trade's instructions than by mentioning that a petition (a copy of which I produce) has been presented against their introduction signed by about 150 Trinity House Pilots of the Port of London. I am informed that many more who would have wished to sign were at sea.

Laxity with regard to side lights would account for collision, &c.

As to the importance of uniformity, provided of course it does not involve a uniform violation of the law and is in the direction of safety, we are all agreed. It is quite possible that the explanation of much of the apparently hard cross-swearing, in collision cases, which has in the past been so severely commented upon, is to be found in the eccentricities in the screening of side lights.

Shipowners' claim to be consulted.

In a recent correspondence with a large steamship company, who protested against being compelled to accept the new instructions against their judgment, the Board of Trade, while continuing to insist that they have in no way altered the spirit of their previous instructions, state that, in deference to the doubts which have arisen in the minds of some shipowners, they are taking steps to have the interpretation of the clauses in dispute clearly determined by Order in Council. I have since heard a rumour that such an order has already been obtained.

I submit that no change in the screening of side lights should, in the first place, have been made without the shipping interest being fully consulted. Having been made, I submit that if, in consequence of criticisms passed on their action by shipowners, the Board was so dubious of the legality of their position as to seek to fortify it by an Order in Council, they ought, by that time at least, to have recognised that they were making a change, with regard to which the shipowners had a right to be consulted.

If in the Board of Trade's opinion our criticisms on the expediency of the change proceed from our ignorance of the subject, we should, I feel sure, be open to conversion. It must be remembered, however, that Foreign Maritime Powers must also be converted before any change can be safely adopted.

The time available will not permit of more detail, and I can but hope that I have made out a case to warrant the serious attention of this Chamber to the matter.

Before concluding I desire to call attention to a recommendation in the Board of Trade instructions to the effect that the side lights should be placed as far forward as practicable. This view is not shared by the captains, pilots, &c., whom I have consulted. The side lights, if placed at some considerable distance abaft the mast-head light, give, in connection with it, a valuable indication of any material alteration in the vessel's course, a fact which seems to have been lost sight of by the Board of Trade.

* Plate XII. † Plate XIII.

App. 6, Nos. 2 and 3.

No. 2.—Copy of Protest by Trinity House Pilots against the rule requiring Lights to be Screened to 4°.

We the undersigned, Trinity House Pilots for the Port of London, do hereby earnestly protest against the danger of violating the International Law relating to the screening of ships' side lights, which law compels all vessels to exhibit the red and the green light showing from right ahead to two points abaft the beam.

The system lately introduced by the Board of Trade of screening the side lights 4° in-board, causes them to be seen across the bow, which we consider misleading, and attended with considerable danger to navigation.

The dark lane this alteration is intended to destroy, is practically non-existent.

No. 3.—Copy of Correspondence between the Chamber of Shipping and the Board of Trade on the subject of the Screening of Ships' Side Lights.

*Ships' Side Lights.*

Chamber of Shipping,
London, 22nd February 1893.

Sir,

It is but lately, that a deputation from the Chamber of Shipping had the honour of being received by you. Among the objects of their seeking an interview, by far the most important was to urge upon you the dangers attendant upon the new instructions issued to your surveyors as to the screening of side lights, to question their legality, and to ask that until further considered the instructions should be held in suspense. The deputation was most courteously received, but your answer on that matter was not favourable. They were told that the new instructions involved no change, that the sanction of the law had subsequently to their issue been obtained through an Order in Council, and in effect that they would be enforced forthwith.

The same answer substantially has been given to questions since asked in Parliament.

The statement that no change in practice is involved does not accord with the judgment or experience of my Council, nor, as it appears to them, is it consonant with the necessity for the sanction of a new order.

Although neither re-assured nor convinced, it was not possible for the deputation to do more than enter the protest of this Chamber, and it is only the extreme gravity of the subject which compels me now to address you again.

Great stress has been laid by your Board in their communications with shipowners, whether individually or collectively, upon the high sanction and authority lent to the new regulations by a resolution adopted at the International Marine Conference, held at Washington in 1889. It has indeed been alluded to by Sir Digby Murray as the source which inspired and promoted the revision.

It was therefore to have been expected that a reference to the protocols of the proceedings of the Conference, even if the arguments adduced in favour of the resolution failed to dispel our objections, would at least be convincing as to the soundness of the conclusions arrived at, provided the premises from which the Conference started were granted.

The resolution ultimately adopted by a majority of 16 to 3, the United States delegates being among the dissentients, reads as follows:—

> "Side lights should be so screened as to prevent the most convergent rays of light being seen more than half a point across the bow."

The discussion presents many points upon which I should like to comment, but my immediate purpose is confined to tracing the grounds upon which the angle of half a point is adopted.

The chain of reasoning is clearly given, *see* page 189 of the Protocols, by Captain Mensing, of the German Navy. "There is," he says, "very little more to be said, except to explain how we came to adopt the angle of half a point."

His explanation which follows may be summarised thus:—

The rule laid down by the Board of Trade for the guidance of their surveyors is that the rays from the two side lights shall cross at a distance ahead of the lights equal to 10 times the beam of the ship. The angle included within the rays converging at such a distance ahead is half a point. Therefore, he concludes, the angle at which each light would be seen across the bow is half a point. No conclusion could sound more plausible or be more erroneous. The angle included by the rays will, it is true, be half a point or thereabouts, but that is the angle formed

by the convergence of the two side lights, and to form such a *combined* angle the convergence of each side light must obviously be only a *quarter* of a point, or one half of the combined convergence.

Side lights converging each to an angle of half a point would intersect at a distance ahead of the ship, not of 10 beams as the Conference supposed, but of five beams, and would include an angle not of half a point, but of a whole point.

The accompanying diagram is intended to illustrate what I have said.

It is sufficiently remarkable that Captain Mensing, and the Conference in his wake, should have unconsciously doubled the angle of convergence of each side light.

It is far more remarkable that a flaw so grave as wholly to vitiate the conclusion arrived at by the Conference, should have passed undiscovered by your Board.

The Conference, believing they were merely endorsing the practice of the Board of Trade, passed the resolution, and the Board of Trade in turn, without adequate scrutiny of the premises upon which the resolution was based, have proceeded to enforce upon British shipowners, despite their protests, the issue of an undetected blunder.

The danger of enforcing a principle which has a fallacy for its foundation, is so obvious that I would again most respectfully urge upon you the expediency of the new regulations being suspended until the question has been thoroughly investigated by a committee upon which the shipowning interest is properly represented.

Let me add that the captains and officers of the Mercantile Marine are practically unanimous in condemning the change as dangerous; so too are the London Trinity House Pilots, of whose protest on the subject I beg to inclose a copy with the names of the signatories attached. The original is in my keeping.

I have, &c.,
(Signed) MARK WHITWILL,
President of the Chamber of Shipping
of the United Kingdom.

To the Right Hon. A. J. Mundella, M.P.,
President of the Board of Trade,
Whitehall.

---

Board of Trade,
Marine Department,
SIR, London, S.W., 25th February 1893.

I AM directed by the Board of Trade to acknowledge the receipt of your letter of the 22nd instant, stating that the resolution of the Washington Marine Conference as to the angle of screening of side lights was adopted under a misapprehension, and requesting that the Order in Council recently made should not come into operation until the question has been thoroughly investigated by a committee on which shipowners are properly represented.

In reply I am to state that the Board will give careful consideration to the points raised in your letter, and will communicate again with you on the subject.

I am, &c.
(Signed) GEORGE J. SWANSTON.

Mark Whitwill, Esq.,
President of the Chamber of
Shipping, Whittington House,
Leadenhall Street, E.C.

---

Board of Trade,
Marine Department,
SIR, London, S.W., 8th March 1893.

WITH further reference to your letter of the 22nd ulto., in regard to the recent Order in Council as to the screening of side lights, I am directed by the Board of Trade to state that the regulation therein contained was based on actual experiments carried out by officers of the Board of Trade, and not on any resolution passed by the Washington Conference.

As the Order in Council is only interpretative, the Board are unable to accede to the request of the Chamber of Shipping.

I am, &c.,
(Signed) GEORGE J. SWANSTON.

To Mark Whitwill, Esq.,
President of the Chamber
of Shipping.

---

SIR, 21st March 1893. APP. C, No. 3.

I HAVE to acknowledge your letter of the 8th instant, in further reply to mine of the 22nd February.

I called your attention in my letter to the grave error, upon which is founded the resolution of the Washington Conference, as to the screening of ships' side lights.

I do not find that I anywhere asserted that the new Order in Council "is based upon the resolution of the "Washington Conference." I have no means of knowing with certainty by what process of reasoning your Board arrived at the conclusions adopted in the Order, or on what representations that Order was obtained.

If, however, you desire now to insist that the new regulations have their origin in independent investigations, uninfluenced by the conclusions of the Conference, I cannot think such a contention accords with the repeated reference made by your Board to those conclusions as having prompted and inspired the revision.

I would further point out that the memorandum drawn up by Sir Digby Murray, embodying the results of these independent experiments, was avowedly a report "on two points contained in resolutions adopted "by the Washington Conference." This in itself supplies proof of the origin of the Order.

It would, perhaps, be as accurate to say that the experiments were based upon the resolution of the Conference, as to say that the Order in Council was based upon the experiments.

The results obtained from the experiments were happily not such as to permit Sir Digby Murray and Mr. Samson to recommend the adoption of the full half-point convergence, however strongly or however little they were predisposed to do so. They adopted, for what reason does not appear, a compromise, and reported in favor of an angle of 4° of convergence. They did not detect the fallacy which vitiated the conclusions of the Conference, and consequently were not aware that they were increasing the angle of convergence previously recognised by the practice of your Board, from, roughly, 2¾° to 4°. There is nothing I submit in the results of the experiments as reported to recommend such an increase.

The recommendation as well as the statements repeatedly made in Parliament, that no change has been introduced, are explicable only on the supposition that your officers followed the lead of the Conference and accepted the delusion involved.

So strong was the delusion that our earlier remonstrances were met by an absolute, I might almost say a passionate, rejection. Though the chocks in every one of their ships were pared down, shipowners were expected to be content with an authoritative assurance that there was no change. Their protests were regarded as the outcome of prejudice. "Numerous criticisms," says a circular issued at this time to the surveying officers of the Board, "have been made, by people "ignorant of the subject, on the Board's recent in- "structions as to the screening of side lights; in one "case, I regret to say, by one of our own officers, who "ought to have been better informed." Departmental Notice, No. 5, Marine Department, Board of Trade, November 1892.

I put it to you, Sir, most respectfully, whether such language was not calculated to stifle the counsel which might otherwise have been received from the Nautical Surveyors of the Board?

You say that the new Order is "only interpretative" of the old. I maintain that in this essential particular of screening the new Order has imposed a construction which reverses the obvious and legitimate meaning of the international rule. The resolution of the Washington Conference was not an interpretation, it was unwittingly an amendment. The new Order is not an interpretation, it is also, as I believe, an unwitting amendment. They both, differing only in degree, introduce a new principle absolutely inconsistent with practical adherence to the international rule, and I would remind you that the U.S. delegates at the Conference strenuously resisted the resolution, because it was inconsistent with and therefore, in their judgment, stultified the rule. *See* Protocols of Proceedings of the Washington Conference, particularly pages 190–191.

Whether, however, the word "interpretative" can by any straining of language be wrested to cover this radical change or not is for my purpose immaterial, as it does not touch the merits of the case. The fact remains that the effect of this "interpretation" is almost to double the angle of convergence as compared with past practice. The kernel of the

App. 6, No. 3.

matter lies in the question, is the conclusion embodied in the new regulations, no matter what fallacy may have underlain it, sound in itself?

In this connection I would again remind you I am supported by the practically unanimous opinion of this Chamber, of the captains and officers of the Mercantile Marine, and of the pilots.

You have refused the request for a departmental committee because the Order is "only interpretative." I confess I fail to grasp the sequence of thought between the decision you announce and the reason you assign for it. The reason is surely not a valid one if the interpretation, as I contend, is wrong and dangerous.

I feel, however, that for the present I cannot advantageously push my protest further except by publishing this correspondence. This I propose to do, along with any further communication you may send me within the next few days.

I am, &c.,
(Signed) MARK WHITWILL,
President of the Chamber of Shipping of the United Kingdom.

The Right Hon. A. J. Mundella, M.P.,
President of the Board of Trade.
Whitehall Gardens, S.W.

## APPENDIX No. 7.

*Papers handed in by Captain Ruthven.*

App. 7, Nos. 1 and 2.

No. 1.*—Copy of the original measurements and calculations to ascertain the angle of convergence of the R.M.T.S. "Ophir's" electric side lights after the chocks had been cut away by the Board of Trade Surveyors, July 1892.

*Explanation.*

The inclination of the chock was got by very careful measurements from the mid-ship line of the bridge.

A line was ruled along the clearly-defined edge of the shadow, and the measurements on the chock were then taken with the greatest care.

From this data the angles and distances were then calculated.

The mean of the two distances on the opposite page, give 311 feet as the crossing point of the lights ahead of the ship.

This distance was measured with a lead line just after dark in Naples, and found to be 303 feet, 8 feet less than that got by calculation.

Had the lights been screened to 4° they would have crossed nearer still at about ·3 of the extreme length of the ship from the stern.

The line of the edge of the shadow produced was found to pass exactly through the position of the centre of the electric lamp L ascertained by measurements from H and G.

No. 2.—Diagram† showing that two vessels of 60 feet beam on diametrically opposite courses and one mile apart, each with the other's red light screened to 4° just shut out from the starboard end of her bridge, would pass 365 feet apart.

## APPENDIX No. 8.

## APPENDIX No. 9.

*Paper handed in by the Chairman.*

App. 9.

REPORT of EXPERIMENTS with SHIPS' SIDE LIGHTS, carried out at SHOEBURYNESS, for SIDE LIGHTS COMMITTEE, BOARD OF TRADE, on the 12th, 13th, and 14th June 1895.

*Description of Lamps.*

Four pairs of lamps were supplied marked A, B, C, D, also a masthead light.
All the burners were constructed for mineral oil. The remaining details were as below:—

| — | A | B | C | D | Masthead. |
|---|---|---|---|---|---|
| Size of wick - - - | $\frac{15}{16}$ in. - - | 1 in. - - | $\frac{7}{8}$ in. - - | $1\frac{1}{16}$ in. full - | $\frac{15}{16}$ in. |
| Number of wicks - - - | 2 | 1 | 2 | 1 | 2 |
| Number of holes in burner for flame. | 1 | 1 | 1 | 1 | 1 |
| Chimney - - - | Yes - - | Yes - - | Yes - - | Yes, wide chimney. | Yes. |
| Description of lens - - - | Dioptric - | Dioptric - - | Fishbowl - | Fishbowl - | Dioptric. |
| Number of corrugations - - | 6 | 10 | — | — | 8 |
| Lens coloured or not - - - | Coloured - | Clear; coloured screen. | Coloured - - | Coloured. | — |

The wicks of all the lamps were arranged at an angle of 44° with the line of the keel.

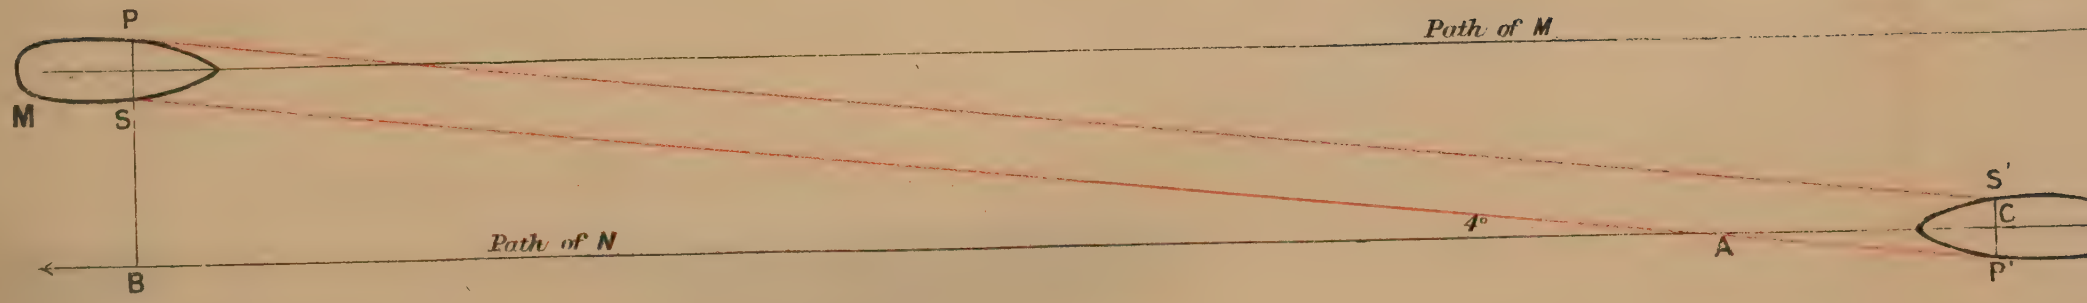
**Nº 2.** *Diagram (not drawn to scale) to show that two vessels of 60 feet beam on diametrically opposite courses and 1 Mile apart, each with the other's Red light screened to 4° just shut out from the Starboard end of her bridge, would pass 365 feet apart.*



$AC = P'C \cdot \text{cotan } A = 30 \times \text{cotan } 4° = 429$ feet - whence $AB = 6080 - 429 = 5651$ ft.
$BS = AC \cdot \cdot \tan A = 395$ feet & this less $CS' = 365$ feet which will be the distance between S & S' when abreast of each other.

*No allowance is made for the fact that if screened to 4° the angle A would exceed this however slightly when the light was shut out, or for the inevitable inaccuracies in steering which if only just shut out would disclose the Red light.*

J. P. Ruthven

*Arrangements.*

The side lights were placed in screens 45 feet apart from centre to centre of wicks, the screens being parallel to one another. The levels of the sands were at the following depths below the flames of the lamps: at 4,000 yards, 19·97 ft.; 2,000 yards, 17·6 ft.; 1,000 yards 16·85 ft.; 500 yards, 15·94 ft. A masthead light was shown at a height of 25 feet above the lamps on the first night, and 40 feet on the two subsequent nights, between the two lights.

The screens were so arranged as to be readily altered by means of chocks to give the angle of screening required. These chocks were all carefully measured and tested before commencing. The screens were laid truly parallel.

The Committee viewed the lamps from distances of 4,000, 2,000, 1,000 and 500 yards.

*Remarks on Observations.*

The weather was very favourable, and the observations may be considered as generally exceedingly accurate.

In considering the results, it must, however, be remembered that observations of this kind, depending upon the judgment and eyesight of different individuals, as well as upon variable atmospheric conditions, cannot be expected to agree exactly to a yard, either among themselves, or with the distances arrived at from theoretical considerations.

With reference, for instance, to the exact point at which a light ceases to show its full power, there is room for considerable difference of opinion among various observers, and the same may be stated as regards its final vanishing point.

The general agreement of these observations is therefore very satisfactory.

*Atmospheric Conditions.*

The weather on all these nights was much the same, atmosphere clear, light airs, not very dark but no moon before midnight, stars faint, cloudy at times. Lights at Sheerness and ships' lights in channel visible, also the Nore and Mouse lights. A slight rain at commencement of the third night, but not interfering with observations.

*Results.*

The results obtained will be found tabulated in Appendix I.

*Remarks* (a). *Observations with Lamps level.*

Those obtained at the various ranges with angles of screening, from outside of wick, of 4, 3, 2 and 1 degrees appear to be most satisfactory.

With reference to those taken when screened at 0° from inside of wick, there appears a discrepancy, the full lights of the respective lamps having crossed over as usual, at ranges of 1,000 and 2,000 yards, but judged not to reach the centre line at 4,000 yards.

It is thought that this observation, as to where the lights cease to be full at 4,000 yards, when screened to 0° from inside of wick might be repeated, if thought necessary, on the next opportunity. This observation was taken after moonrise, when the lamps were altering their appearance, owing to the increasing light and also to a tendency in the atmosphere to thicken, and several observations taken subsequent to this one, were afterwards decided to be unreliable, and erased from the record.

It is pointed out that the screening at 0° from inside of wick, is actually a somewhat wider angle than 1° from outside of wick, being equal to about 1° 12′ measured from the latter point.

(b.) *Observations with Lamps heeled.*

The screens were heeled by being merely canted over on their own bases to the required angle, the relative heights of the lamps above plane not being altered.

The results obtained will be found in the table, Appendix I.

*Comparison of Lamps of Different Patterns.*

App. 9.

On 13th June 1895 the A, B and C lamps were placed in succession in the screens, screened to 4° and observed from 4,000 yards.

Taking the value of the A lamps as 10 each, numerical values were assigned to the remainder as below—the green being compared with the green and the red with the red—

| | Port. | Starboard. |
|---|---|---|
| A Lamps - - | 10 | 10 |
| B „ - - | 11 | 9 |
| C „ - - - | 5 or 6 | 1 |

the above six lamps were then removed from the screens and placed in a row, showing about 5 points, at 10 ft. interval, but in an unknown order.

The Committee were able to pick out all the respective lamps without difficulty, and their observations proved to be correct.

The Committee then moved to 2,000 yards and decided that there was no change in the relative values of the six lights exhibited.

The D lamps were then substituted for the C, and were found much superior; the numerical values as judged by one of the observers being Port 9, Starboard 7½.

An officer was sent back to 4,000 yards and reported that both D lamps were distinctly visible at that distance through glasses, showing a good light equal in intensity to the A lamps (which were then showing screened to 4°), but smaller.

"*Dark Lane.*"

With the A lamps in the screens, and screened to 0° from inside of wick, the Committee on 13th June, 1895, drove straight down the centre line from 1,000 to about 480 yards, at which point the line had to be left owing to the soft mud. During this observation both lights were plainly visible all the way, bright, clear and of good colour.

On 14th June, 1895, by the use of special broad-wheeled wagons, the observation was continued, the lamps being screened as above, and the Committee drove straight in on to the lamps from 500 yards, and found that both lamps remained visible on the centre line, till within about 60 yards of the lamps.

On altering the screening, it was found that both lights could be seen on the centre line at distances of—

Screened to 2° outside of wick - 44 yards.
„ 4° „ - 33 „

With reference to these observations, at short ranges there is a quantity of light from the lens visible even after the entire wick is shut out by the screen. A table of the angles subtended at the screen by the exterior of the glass of the lanthorn as compared with the nominal screening is attached.—Appendix II.

*Diagrams.*

Six diagrams drawn to a scale of 50 yards to an inch, showing graphically the results of the observations taken, are attached to this Report. These also show the lateral distances, marked in figures and the angles subtended by those distances at the wick of the lamp are also marked.

It will be observed that at 4,000 yards the vanishing point of each light corresponds very closely with the angle to which the lamps were screened in each observation, but that at the longest ranges, the light had been waning in intensity for some distance short of this.

At the shorter ranges the lights show comparatively wider, as might be expected, as the rays from the lens here begin to tell.

Fred. Elmslie, Major, R.A.
Assistant Superintendent of Experiments.

Experiments carried out at Shoeburyness on 12th, 13th, and 14th June, 1895.

Price K. Lewes, Lt., R.A.

*Explanation of the Diagrams.**

The distances from the centre line to the points of full light and disappearance are numbered in yards.

Lines are drawn from these points, converging on the centre line. The angles written against these lines are the angles made with the centre line, by a line joining the figured point and the wick of the lamp itself.

The distances to lamps in inches, as shown on the diagrams, should be measured in each case from the figure under consideration; as all the diagrams at each range should be super-imposed.

The lamps, on this scale, should be placed 0·15 ins. on either side of the centre line or 0·3 ins. apart.

Fred Elmslie, Major, R.A.
Assistant Superintendent of Experiments.

*Papers handed in by Captain Thomson.*

## No. 1.—Side Light Experiments at Silvertown Telegraph Works on the Nights of April 10th and 23rd, and May 6th, 1895.

The lights were exhibited from a building close to the river bank and viewed from the Dockyard wall on the opposite side of the river, the distance being 572 yards. The object of the experiments was to ascertain practically to what angle the diffused or scattered light from the lens would be visible at this distance with various illuminants and with angles of screening from 0 to 4 degrees.

At the distance at which the lights were viewed 1 minute of arc = 6 inches.

The sign + after an angular distance means that the light paled or cut off on the open side before the screening or zero line was reached.

Notes.—Lanterns, "Harvie" No. 22,592 (starboard) and No. 22,593 (port).
Both lights exhibited at the same time. The *Red* light appeared the brighter of the two, but the *Green* seemed more persistent, being visible to as great a crossing angle as the *Red*.
*Weather*, very fine clear starlight, no haze or moonlight.
When considered *Fair*, red light appeared equal to a good barge's red light in mid-river. The red light at its full power seemed equal to a large steamer's red oil light in mid-river.

May 6th, 1895.—Experiments with Colza Oil in Harvie Lantern, No. 22,592; double flat wick, fore and aft; width 44 mm. = $1\frac{3}{4}$″, breadth across wicks 28 mm. = $1\frac{1}{16}$″.

| 2 | 9 44 | „ 1° „ | 1 47 | 2 12 | 2 34 | 4 8 | | 7 | 10 0 | „ 1° „ | 2 0 | 2 12 | 2 42 | 4 24 | |
| 3 | 9 30 | „ 2° „ | 2 54 | 3 19 | 3 42 | 5 25 | | 8 | 9 57 | „ 2° „ | 3 0 | 3 16 | 3 48 | 5 14 | |
| 4 | 9 34 | „ 2° from outside | 1 24 | 1 54 | 2 18 | 4 0 | Cut off at first very sudden. | 9 | 9 50 | „ 2° from outside | 1 19 | 1 53 | 2 36 | 4 0 | |
| 5 | 9 40 | „ 4° „ | 3 30 | 3 56 | 4 8 | 6 0 | | 10 | 10 3 | „ 4° „ | 3 36 | 4 0 | 4 20 | 6 0 | |

Notes.—The *Red* light at its best about equal to a coasting steamer's light abeam in mid-river, but it is not equal to the 16 c.p. electric light.
The sudden cut off of the colza light probably due to the double wick being fore and aft in the lantern.
The double wick subtends an angle of 1° 21′ at the slide. *Weather*.—Fine and clear, moonlight.

Anthony S. Thomson.

| 19 | 10 18 | Curl | 18 mm. | 32 | Right angles | 104 | | Green<br>Red | Red and Green shown simultaneously 4 feet apart. | 0 0<br>0 0 | 0 8<br>0 8 | Not taken | | Both lights cut off at the screening line; both appeared fair when viewed from the central line. | |

The + sign means that the light cut off before the screening line was reached.

Notes.—One lantern only used in all the experiments except the last, when the red and green lights were shown simultaneously from similar lanterns.

As the tangent to one degree for radius 572 is 10, one minute of arc = 6 ins. at the distance from which the lights were viewed.

The colza and mineral oil lamps supplied for use in these lanterns, when tested photometrically, were found about equal to a 16 candle power electric lamp.

## APPENDIX No. 11.

App. 11.

*Paper handed in by Captain Wilson Barker.*

REPORT of EXPERIMENTS with SIDE LIGHTS.

A series of experiments were conducted with common lamps without any special refinements, except that the point right in the fore and aft line between the lamps —to which imaginary line the screens were parallel— was most carefully determined, and it is considered that any errors are within + or — 10 feet, allowing a liberal estimate.

The lamps were those fitted without chimneys, and burning paraffin. The shells were galvanised, and the "lenses" or fronts were of plain stained fish-globe glass. The wicks were single and 1 in. in breadth. The lamps were arranged in screens on a platform back to back, the space between their backs being 7 inches.

The screens were regulation size, and cut off screens were formed of block tin. The base of the screen was carefully marked out with the angles, and every care taken that the cut off was absolutely accurate.

The lamps were carefully trimmed and set by myself, and experiments conducted after they had been alight and in position about half-an-hour.

A good pair of binoculars were used for sighting.

The wicks were placed at right angles to the fore and aft line. No masthead light was used, and no other lights were about to distract the attention.

Both nights were fine and cloudy, and would be considered medium seeing nights.

The distance from the lights to centre of line where observations were taken was 3,560 feet.

While on the ground observing a great difference could be observed between the behaviour of the lights (although the flames inside were as nearly similar as possible), the red seemed to glow all over as a red ball, the green not at all; the light in the green lamp even at this distance forming almost a point of light. Up to the last glimmer the red light could be seen as red, not so with the green, as at a certain point while still being visible it lost its greenness, and might be described as a dirty white light, and an observer would possibly think it was the light from the binnacle. The points observed to are those where colour ceased to be visible to the glasses.

It is very striking how much more across the bow the red light is visible on the green side than the green is on the red side. The Table shows this clearly.

It might be expected from this that more collisions would arise from altering the course to starboard, as the present law requires, than if the law required the course to be altered to port. The diagram* clearly shows this, and its explanation.

TABLE illustrating the RANGE of the RED and GREEN LIGHTS on fore and aft LINE.

+ Means that it extended over the 10 points the amount given.

— Means that it was less than the 10 points by amount given.

Thus at + the red light was 640 feet past the fore and aft line while the green was only 60 feet.

30th June 1895. D. WILSON BARKER.

## APPENDIX No. 12.

App. 12.

REPORT of FURTHER EXPERIMENTS with SHIPS' LIGHTS, carried out at SHOEBURYNESS, for SIDE LIGHTS COMMITTEE, on July 25th and 26th, 1895.

*Lamps used.*—The lanthorns were the same as those used by the Committee in their previous series of experiments on June 12th to 14th, 1895, and described in the Report dated June 18th, 1895.* On this occasion, however, they were fitted, in addition to the oil burners, with electric incandescent lamps of 50, 32, and 16 candle power. The distance of the outside edge of the filament from the side of the lanthorn, and the angle made by the filament with the back of the lanthorn, compared with the position of the outside edge of wick and the angle of wick in the oil lamps.

The B pattern of lanthorn, having a clear lens and a coloured shade, were used to test two tints of green shade, which will be distinguished in this report as light and dark shades respectively.

*General Arrangements.*—Were practically the same as described in report dated June 18th, 1895, except that the masthead light was now raised to a height of 45 ft. above the side lights. The committee viewed the lights from distances of 5,000 yds., 2,000 yds., and 500 yds.

*General Remarks.*—The observations on this occasion were made with a large number of variables, including distance from lights, angle of screening, nature of lamps, whether oil or electric, the candle power of each respective lamp, and in the case of the starboard lanthorn, different tints of green shade.

In consequence of this, it is difficult to tabulate the results, but, for convenience of reporting, the observations have been divided into series according to their nature as below. The observations of :—

*Series* I.—Refer to the relative values of the respective lights when seen from certain points at which the observations were taken.

Those of *Series* II. refer to the distances each side of the centre line at which the lights were seen full, and also finally disappeared.

Those of *Series* III. refer to continuous observations taken while driving down the centre line towards the lights.

Those of *Series* IV. were special, having reference to the observations reported as doubtful in the report dated June 18th, 1895.

The figures and distances given are, with one or two exceptions, those judged by the Committee.

Although classified as above, the order of the various observations has been preserved in this report as some of the remarks made are based upon the experience of more than one observation, sometimes of different natures.

*Atmospheric Conditions.*—The weather was favourable, nights fairly dark and clear, sky overcast to clear, the former predominating. Nore Light, Mouse Light, and lights in channel plainly visible on both nights. No moon.

* *See* Appendix 9.

* Plate XXIV.

App. 12.

*Observations taken on July 25th, 1895.*

*Series* I.—Relative value of lights.

(a.) *Point of Observation.*—On centre line of ship at 5,000 yards from lights.

*Nature of Light shown.*—Side lanthorns B pattern, with electric lamps, 16 candle power.

Masthead lamp at 45 ft. above side lights, oil lamp.

*How screened.*—Four degrees from outside of wick.

It was observed that the light green shade in the starboard lanthorn gave a more luminous light at this distance than the dark green shade.

*Valuation of Brightness of Lamps.*—Taking the masthead lamp (oil) as value 10 the side lights with 16 c.p. incandescent lamps were valued :—

| | |
|---|---|
| Port - - - | 10 |
| Starboard (dark green) - | 7 |

With 32 c.p. incandescent lamps :—

| | |
|---|---|
| Port - - - | 14 |
| Starboard (dark green) - | 9 |

With 50 c.p. incandescent lamps (observed from same spot but screened to 0 degrees inside of wick), the values were judged :—

| | |
|---|---|
| Port - - - | 16 |
| Starboard (light shade) | 11 |

Both were lamps of good colour, luminous and unmistakeable :—

| | |
|---|---|
| Starboard (dark shade) - | 9 |

It was noted that the masthead light should not be too strong compared with the others, as too strong a masthead light tends to apparently dim the side lights.

*Series* II.—The Committee also took observations as to the distances, on each side of the centre line, the side lights with different candle powers showed full power and ceased to be visible, respectively, at this distance, and also at 2,000 yds. The results of these observations will be found in table A.

*Series* I.—continued. *Point of Observation.* On centre line of ship at 2,000 yds. from the lights.

*Nature of Side Lights shown.*—B.lanthorns (light-green shade, in starboard lanthorn) 16 c.p. electric lights.

*How screened.*—0 degress inside of wick. Values adjudged :—

| | |
|---|---|
| Masthead - - | 10 |
| Port - - - - | 9 |
| Starboard - - | 7 or 8 |

Oil lamps now substituted for the electric, all other conditions the same.

Values adjudged.

| | |
|---|---|
| Masthead - - | 10 |
| Port - - - - | 8 |
| Starboard - - | 6 |

The Committee, after noting the appearance of the lamps at this distance with candle powers of 32, 50 and 16 respectively, and having previously observed these candle powers from distances of 5,000 yds., remarked that :—(1.) The 32 c.p. lamps seemed to give a good and sufficient light. (2.) The 50 c.p. is not so markedly superior to the 32 c.p. as to render the difference of great importance, but it appeared to them that 50 c.p. should not be exceeded. (3.) The 16 c.p. lamps were markedly inferior to the 32 c.p. lamps.

*Series* III.—With the B lanthorns with oil lamps, and screened to 0 degrees inside of wick, the Committee drove down the centre line from 2,000 yds. direct to the lamps, and saw that both lights were visible the whole distance until the foot of the beach was reached, about 65 yds. from the lamps.

*Observations taken on July 26th, 1895.*

*Series* IV.—With the A lamps (oil) screened to 0 degrees inside of wick and viewed from the centre line at 4,000 yards from the lights, the Committee judged that both lights showed practically their full power on the centre line.

*Series* II. (resumed). B lanthorns electric 16 c.p. incandescent lamps, screened to 4 degrees outside of wick, and observed at 4,000 yards.

For results *see* table A.

The Committee noted that the electric lamps seemed a great improvement over the oil.

The light green shade was unfortunately broken accidentally. The broken shade was used for a short time, then as rays of white light got through the cracks a shade of "standard" green, which was nearly a match, was tried, and used for one observation, but found unsatisfactory as it did not fit the lamp and allowed of the escape of some white rays round its edge.

Observations were therefore continued with the dark green shade.

The observations made with the broken and ill-fitting shade are marked in Table A.

*Series* I.—*Relative values of lamps* (resumed).

*Point of Observation.*—On centre line of ship at 4,000 yds.

*Nature of Light shown.*—B lanthorns electric 16 c.p. lamps. Dark-green shade in starboard lanthorn. Masthead light, oil.

*How screened.*—0 degrees inside of wick.

Values adjudged :—

| | |
|---|---|
| Masthead - - | 10 |
| Port - - - | 8 |
| Starboard - - | 3 |

Starboard lamp changed to 32 c.p.

Value increased to 7.

The masthead now changed to electric 16 c.p. The Committee considered this lamp superior to the oil one, while it did not sensibly diminish the brightness of the green and red. They value the masthead lamp now at 12.

The three lamps thus stood as follows :—

Masthead 16 c.p., value 12.
Port 16 c.p., value 8.
Starboard 32 c.p., value 7.

A 50 c.p. lamp was now substituted in the starboard lanthorn, the value of which was again adjudged to be 7.*

The masthead was now raised to 32 c.p. and the Committee were of opinion that the effect of the brighter masthead light was to apparently dim the green and red to a material degree.

*Series* II. (resumed). At 500 yds.

*Lights.*—Masthead electric 16 c.p. :—
Port electric 16 c.p.
Starboard electric 50 c.p.

*How screened.*—0 degrees inside of wick.

For results *see* table A.

*Series* III.—With the lights as above, the Committee drove down the centre line from 500 yds. direct on to the lamps, and, as on the previous occasion, found that both lights were visible all the way until the foot of the beach was reached.

The distance from the lights on the centre line, at which both lights ceased to be visible, was found to be 55 yds.

*Diagrams.*—Four diagrams† are enclosed based on the figures in the report.

Fred Elmslie.
Major, R.A.
Asst. Supt. of Experiments.

Shoeburyness,
July 31st, 1895.

* It is singular that in the case of this lanthorn with this shade, the same value has twice been allotted to the 50 c.p. lamp as to the 32 c.p. *See* observations made on July 25, 1895. Series I.

Fred. Elmslie, Major R.A.,
Asst. Supt. of Experiments.

## APPENDIX No. 13.

App. 13, No. 1.

*Papers handed in by Sir D. Murray.*

No. 1.—Experiments made in 1892 to determine the effect of Electric Light on the colour of the Green Glass.

In consequence of the representations of the Russian Naval Attaché as to the effect of the electric light on the green side light of the Russian Imperial yacht, I promised to thoroughly investigate the subject.

I requested Mr. Samson to make some initial inquiries and experiments, and as these latter appeared to show that the electric light did, to a certain extent, neutralise the colour of the green slide or lens (as the case may be), I determined to thoroughly experiment with a view to ascertaining definitely the effect of the electric light of different degrees of intensity on the green glass.

Hearing that Sir Donald Currie & Co. applied electric light of very considerable candle power to their side lights, I wrote to that firm requesting that they would give Mr. Samson facilities for inspecting their lights, and it is owing to their kindness and courtesy and the able assistance rendered by the [illegible] that it has been possible at once to arrive at a solution of this question.

The Board of Trade [illegible] standard side lights, together with the standard green [illegible] as approved by the Admiralty and the Board of Trade, to Sir Donald Currie's office at Billiter-walk, and at 5 p.m. on Wednesday, November 2nd, the trials took place before Captain Rogestvensky, the Naval Attaché to the Imperial Russian Embassy, Mr. Samson, and myself, and were of the most conclusive character.

The lamps tried were three in number, viz.:—

(1.) An electric side light, manufactured by Messrs. Chance Brothers, of Birmingham, having a green slide of a different colour and deeper tint than the darkest shade of the two Board of Trade standard colours.

(2.) An electric side light, having a green slide of the same tint as the darker of the two Board of Trade standard colours.

(3.) The Board of Trade standard oil lamp, having a green slide of the same tint as the lighter of the two Board of Trade standard colours. I was anxious to replace this slide with one of the darker tint, but no spare slides would suit the particular lamp, and as our experiments subsequently showed this was not material.

It was raining during the time the experiments were being carried out, but this did not at all affect the comparisons between the three green lights, although it considerably affected the colour of the white mast-head light, giving it a reddish tinge.

Apr. 13, Nos. 1 and 2.

The electric side light of Messrs. Chance showed a good colour throughout the whole of the experiments; though the green slide of this lamp was of a deeper colour than the darkest of the Board of Trade standard tints there was only a very slight perceptible difference between its colour when lighted by electricity and the colour of the oil lamp which had a slide of the lightest of the Board of Trade tints.

The conclusions Mr. Samson and I have arrived at are as follows:—

In the case of electric side lights neither of the standard greens are dark enough, and the colour should either be determined by experiment, in which case the colour of the side light at the particular candle power it is intended to use should not show lighter than that of a full-sized oil lamp fitted with the lightest of the two standard tints of green, or the shade of colour which Messrs. Chance have, in consultation with Sir Donald Currie & Co., manufactured for this particular lamp on board the "Roslin Castle" should be adopted.

We think it desirable that a number of slips of glass of this colour should be obtained from Messrs. Chance for the information of the Board's officers, and through them of the shipowning public, and that a cautionary circular should be sent out to the surveyors to the following effect:—

"It having come to the knowledge of the Board of Trade that the two standard green tints adopted by them for oil lamps are not applicable to electric side lights, surveyors are informed as follows:—

"In the case of electric side lights neither of the standard tints of green are dark enough, and the colour should either be determined by experiment, in which case the side light should not show of a lighter colour than that of a full-sized oil lamp fitted with the lightest of the two standard tints of green glass, or the shade of colour which Messrs. Chance have adopted in consultation with Sir Donald Currie & Co. in the starboard side light of the 'Roslin Castle' should be adopted.

"Samples of these glasses are forwarded herewith, and surveyors should make this information as public as possible."

We append a table showing the experiments.

| Description of Light. Starboard Electric Side Light with a specially dark-tinted Slide, by Messrs. Chance Brothers. | Description of Light. Starboard Electric Side Light with a Slide of the darker Tint of the two Board of Trade Standards. | Description of Light. Board of Trade Standard Starboard Side Light, burning Mineral Oil with a Slide of the lighter Tint of the two Board of Trade Standards. |
|---|---|---|
| Candle power. | | |
| 16.—Good colour | Pale in colour - | Very good colour. |
| 32.— „ - | Too pale in colour | — |
| 50.— „ - | „ „ | — |
| 100.— „ - | Not tried. | — |
| 200.— „ - | „ | — |

All the electric lights were incandescent lights.

As compared with the oil lamp fitted with the light-green slide, the electric light fitted with a slide corresponding to the darker standard green was too pale, and with 32 and 50 candle power was nearly white.

Messrs. Chance's light, though fitted with a specially dark slide, showed only just a shade darker colour than the oil lamp. The difference in candle power did not seem to further effect its colour, *i.e.*, its colour with 200 candle power was as good as with only 16 candle power.

DIGBY MURRAY.
PETER SAMSON.

No. 2.—GENERAL CONCLUSIONS as to the SCREENING of SIDE LIGHTS.

1. That lights ought to converge to as large an angle as may be consistent with safety, and that this angle should not be less than 4° and as far as practicable uniform in all ships.

2. It matters but little in rivers or narrow channels whether the vessels navigating up and down the channel have side lights at all, or, if they have, to what angle they may be screened, but it is very material in the case of small vessels which are crossing the channel backwards and forwards.

3. If it is considered unsafe for vessels navigating rivers and narrow inland waters to have their lights screened to the same angle as at sea, this may be readily provided for by placing the lamps back to back at the stem of the ship, with a screen between them regulated to any angle which may be thought desirable and of sufficient length to prevent the lights from blending, a position in which they could not, of course, be carried at sea. I do not, however, consider this necessary.

4. As the condition of the atmosphere, the encrustation of salt on the lenses, the vertical position of the flame with reference to the ship's heel, the colour of the glass, and whether the lens itself is coloured or whether the colour is produced by coloured slides will all have an appreciable effect on the angle at which the light will be visible from the middle line, it would on these accounts be undesirable to screen the lights to too fine an angle. Let me put the fine angle of screening hypothetically, and suppose that it is determined to screen the lights to an angle of 2° measured from the outer edge of the wick.

Those in favour of this angle of screening would probably be of opinion either that the regulations should be added to, or that there should be an implied instruction to the following effect:—

Steamships sighting a red light fine on their port bow should, unless it is rapidly changing its bearing, port to it.

Steamships sighting a green light fine on their starboard bow should, unless it is rapidly changing its bearing, starboard to it.

Hypothetically it is safe to port to a red light on the port bow, and to starboard to a green light on the starboard bow. Whether in the case of lights being screened to an angle of 2° this latter would be safe in practice is a point for consideration.

It is impossible for the surveyor to screen lights on board ship with absolute mechanical accuracy, and to solve the foregoing problem it will be necessary to consider the method adopted to obtain the required angle of convergence, and also the limits of error both inwards and outwards from that angle.

The usual way of fitting the screens parallel to the keel is as follows:—

A line is stretched between the centre of two masts where these are available, and then a wood batten is squared across from this line, both on the port and starboard side, to the fore and after sides of the screens.

If two masts, or a mast and funnel are not available, a measurement is taken of the entire width of the ship in the required position, and the middle line struck from this and wood battens used as before.

If either of these methods is intelligently carried out the limit of error may be about ½° each way, that is to say, if it is required to screen lights to, say, 2°, they may in one ship be screened to 2½° and in another to 1½°, though in both supposed to be screened to 2°.

Supposing A.* to be the vessel having her lights screened to 1½° and B. to be the vessel having her lights screened to 2½°.

Then A. in the position shown in the diagram sees both the side lights of B. and ports.

B. sees only the green light of A. and starboards.

The lamps are usually clamped to the screens, they have frequently a little play, and sometimes are not quite parallel to the screen, but the error from this cause is probably merely nominal.

If wood screens are fitted they are liable to warp and in one case brought under my notice to an extent of 1 inch in a length of 42 inches—equal to an alteration in the screening of about 1° 21′ 45″.

When the side lights are carried on stanchions or davits the screening is very liable to get deranged by ropes fouling them, their coming in contact with dock sides or receiving blows from a sea, and this to a very considerable extent.

The foregoing are reasons for not screening lights too finely as it is evident that although nominally screened to any particular angle it by no means follows that this is accurately the case.

I am extremely anxious to understate and not to overstate my case, and, although in practice a considerable error may arise, I shall confine myself to the ½° of error each way which the present methods admit of, even when intelligently carried out, and this is equivalent to an error of about $\frac{3}{16}$ of an inch, more accurately

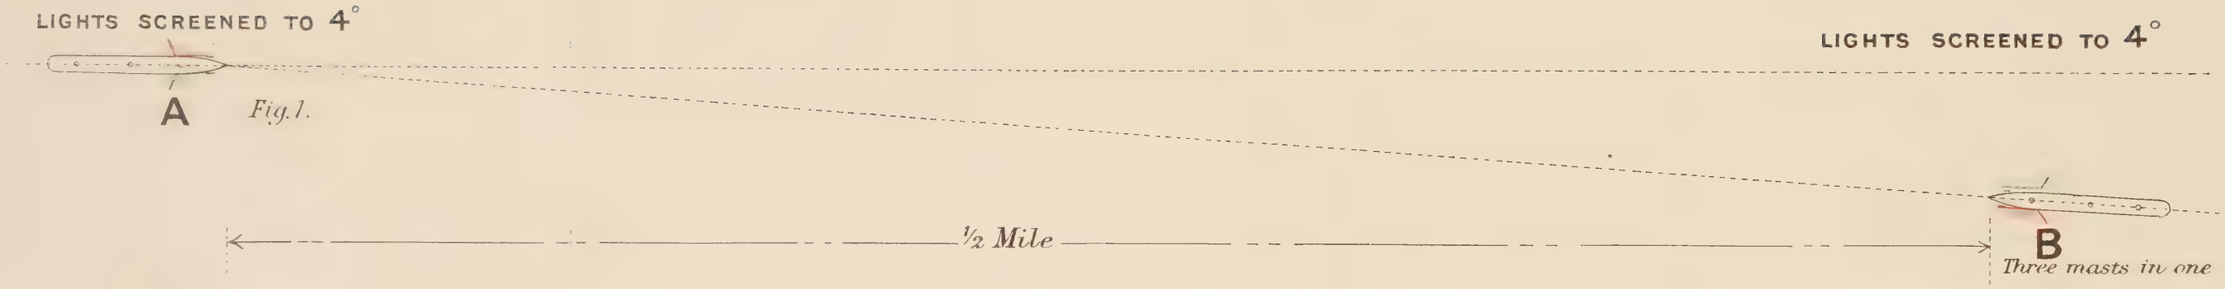

*Fig. 1.*

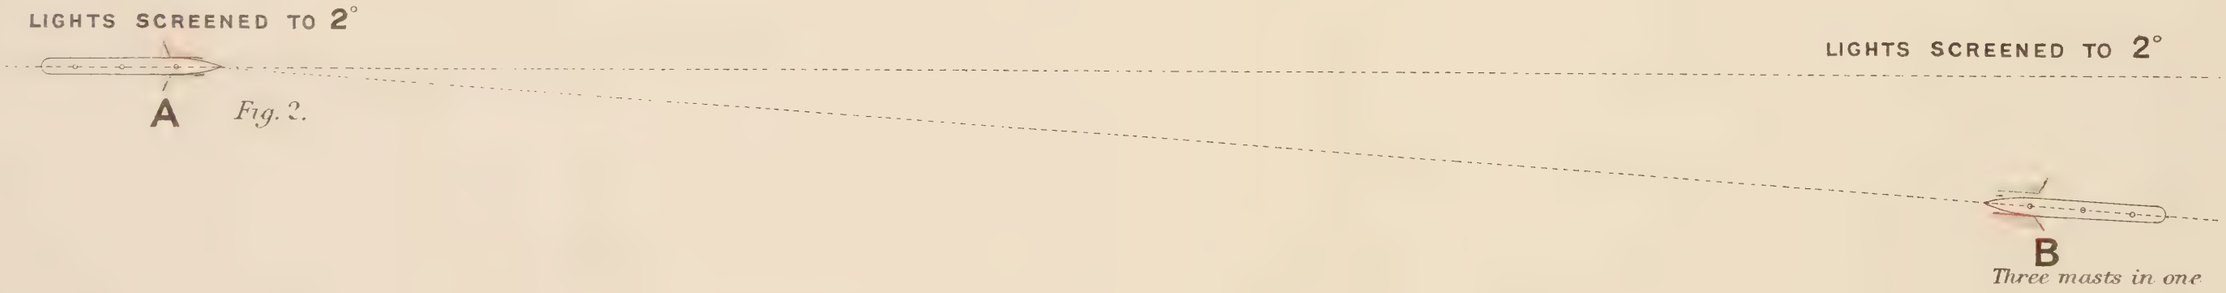

*Fig. 2.*

*Scale of Feet.*

·314 in measuring the distance from the middle line. *See* diagram, which I think abundantly proves that it is not necessarily safe to starboard to a green light fine on the starboard bow. I think in such a position the only safe course is for both ships to port. In addition to the liability to error from the causes previously alluded to, large angles of permanent heel, often met with in the case of timber laden and grain laden ships, may produce a further error of ½° or over in consequence of the flame always remaining vertical although the lamp is inclined.

If the lights are to be screened to a smaller angle than 4°, then, in my opinion, there should be international agreement, and even then I think it would be fraught with danger.

At one time I thought lamps ought to be screened to as small an angle as possible consistent with the full volume of light being visible at a reasonable distance ahead of the ships. Further investigation has altered my views, and, if I was perfectly autocratic in the matter, I should increase the angle to 4½°.

5. At the time of our experiments Mr. Samson and I were of opinion that the red light might be screened to 3° and the green light to 4°,* and we then discussed the question as to whether it was desirable to screen the two lights to two different angles, and the conclusion we arrived at was that it was on the whole preferable to screen them alike. It does not, I think, matter greatly to what angle the lights of large passenger steamships are screened, their speed will enable those in charge of the deck to give all other vessels a reasonably wide berth, but it is of the utmost importance to the commanders, and indirectly to the owners of these large steamships, that the slower and smaller class of vessels should be efficiently lighted and, as far as practicable, uniformly screened.

The exact angle to which side lights should be screened will always be a matter of opinion, but to form a fairly correct judgment it will be necessary to determine in the first place what is nearly end on and to screen the lights in such a manner that there shall be no doubt when ships are in these relative positions.

In the second place to determine the angle of screening necessary to enable the full volume of light to be seen ahead of the vessel, so that in foggy, hazy, or thick weather the rays of light may penetrate as far as possible.

* *See* Report of the experiments at the Glengall Iron Works. Appendix 2, No. 5.

The outcry against the action of the Board of Trade has been for the most part the outcome of misapprehension, and the result of critics assuming to themselves a knowledge which they did not possess. No master of a ship and no pilot has, from the mere nature of his calling, a knowledge on this particular subject, and it is impossible for either one or the other to argue accurately from an assumed knowledge of the screening of particular ships with reference to which they have no precise information. My own knowledge on the subject, was, when I joined the Board of Trade in 1873, of a very limited description, and what little I know has been acquired since, and the only fear I now have is that I, and the members of the Board of Trade staff, who together with myself have given evidence, have inadequately conveyed to the minds of the Committee all the endless phases of this most complex and difficult subject.

App. 13, Nos. 2 and 3.

D. Murray,
May 17, 1895.

No. 3.—Memorandum on Ships Meeting nearly end on at Night.

The conditions of steamships approaching one another, end on or nearly end on, by day and those applicable by night are widely different.

In figures 1 and 2,* when the vessels are approaching one another by day, their directions would be known, and they would probably both port, so as to give one another a sufficiently wide berth. It might be held that the vessels marked A. should get out of the way of the vessels marked B., but I think it admits of argument that B. is not a crossing vessel on A.'s starboard *side*.

In figure 1, supposing the two vessels to be approaching one another by night, and their side lights to be screened to an angle of 4°, their directions would not be known to one another, but both would port. In figure 2, supposing the lights to be screened to an angle of 2°, A. would see both the side lights of B., and would port. B. would only see the green light of A., and would probably starboard. This, in my opinion, shows the absolute necessity of determining what is nearly end on, before coming to any definite conclusion as to the exact angle of screening.

| Sultan | 39½ | 14 | |
| Neptune | 37 | 30 | |
| Calliope | 22 | 13 | |

No. 3.—Admiralty Rule as to Screening.

The screens ahead should be so fitted that an observer approaching the ship from right ahead would see the full rays from both lights up to a point from 200 to 150 yards before the stem; between which point and the ship the lights should appear dim, gradually disappearing as the bow of the ship is approached.

The smaller distance of 150 yards is preferable for ships with small beam, or ships with small transverse distance between the lights, and the greater of 200 yards for ships with greater distance between the lights.

The lights should be tried in place to see if the before-mentioned conditions are fulfilled, and, if not, the necessary alterations to the fittings should be made.

# APPENDIX No. 16.

App. 16.

*Paper handed in by Mr. Taylor.*

Board of Trade Office, Greenock,
18th January 1895.

Sir,

With reference to your letter of the 11th instant to Mr. Rowley re-screening of side lights in old vessels, I beg to submit the accompanying table, giving the actual results obtained by me during the year 1893, in 100 vessels, as taken from my private note books in consecutive order, and which consequently can be fully substantiated. In the case of each vessel I ascertained from the master or chief officer that the screens had not been previously dealt with by any other surveyor under Board's Minute 2,220 of 1893; therefore, I am quite sure that the subjoined table gives the actual angles of convergence in the light screens of 100 vessels taken indiscriminately, and I think it may be taken as a good example of the general condition of vessels' light screens previous to the present regulations coming into force.

In each case I inquired of the master or officer in charge of the vessel whether the side lights converged, and it is a remarkable fact that 94 per cent. of them were under the impression that the rays of light showed ahead in lines parallel to the centre line of the vessel, although they had been sailing vessels for years with side lights in many instances converging much in excess of what is required by the present regulations.

I remain, &c.
T. D. Taylor,
Shipwright Surveyor.

Principal Officer,
Glasgow.

Between 3° and 5° = 67 ,,

# APPENDIX No. 17.

App. 17, Nos. 1 and 3.

*Papers handed in by the Chairman.*

No. 1.—Letter from the Shipmasters' Society.

60, Fenchurch Street, London, E.C.
7th August 1895.

Sir,

The Committee of the Shipmasters' Society beg leave to place the following suggestions before the Departmental Committee on side lights, and respectfully to ask for its consideration of them, for the purpose of introducing uniformity of practice, as far as that is possible; and with a view to action being taken thereon, in the form of recommendation or otherwise, as may seem expedient to the Committee.

*Ships' Signal Lights and the placing of them.*

That the masthead and side lamps and lanterns in all vessels should be of uniform types mechanically—that, taking into account the illuminants used, the lenses of side lanterns should be of uniform tints, and the lights of uniform power.

That all steamers should carry their masthead and side lights placed to form isosceles triangles of fixed proportions, having angles of about 65° at the base and 50° at the apex; in other words, the masthead lights above the side lights, at heights in fixed proportion to the beam.

That all steamers should carry their side lights *either* abaft the masthead lights at a fixed angle with the perpendicular; or, the three lights *in* a vertical plane, or the side lights before the masthead lights, at a fixed angle with the perpendicular.

That the deck and cabin lights of electrically lit steamers, should be screened on the fore side and abeam to prevent the flood of white light from swamping the colour of the side lights.

Under existing regulations there is no limit to the height above the decks at which the side lights may be carried.—By order of the Committee,

A. G. Froud, Secretary.

The Secretary, Side Lights Committee.

---

No. 2.—Letter from the Merchant Service Guild.

22, Canning Place, Liverpool,
May 1895.

Sir,

I am directed to inform you that the Guild have, after most careful consideration, come to the following conclusions on this matter, and beg respectfully to submit them to your Committee as being those of purely representative captains and officers of the Merchant Service, upon whom alone devolves the duty and responsibility of carrying out the rules of the road at sea:—

With regard to the Order in Council relating to the screening of side lights, dated 30th March 1893, the Guild are of opinion that a great deal of the agitation against it has been caused by a superficial and theoretical knowledge only of the subject, and while in no way approving of the action of the Board of Trade in this matter, they feel that the Order in Council referred to has not in any way interfered with the practical working of vessels at sea. They would, however, unhesitatingly state that, practically speaking, there is no "dark lane" in the sense as meant, and that therefore the Board of Trade had no cause in harassing British shipping by enforcing needless expense upon the shipowners. They also believe that the squinting side lights, as at present in force in this country, would place British captains and officers at a serious disadvantage in any collision inquiry before a foreign tribunal.

While considering this matter it has been thought that much more important points might be included in the deliberations of the Committee, viz.: the position, colour, &c., of the side lights, and they would humbly offer the following suggestions:—

(*a.*) That the side lights should be uniformly placed in all vessels. The Guild would recommend that in the case of steamers the side lights should be placed as far abaft the mast head light as that light is above the plane of the side lights, and in sailing ships they should be so fixed as not to be in any way obscured by the clews of the foresail.

(*b.*) That standard shades of glass should be adopted for the side lights. Great difficulty is often met with in "picking up" a green light, owing to the shade of glass used being in many cases very light and in close resemblance to a bright light. For a standard shade of green the Guild would recommend that in use on the East Goodwin light ship.

(*c.*) In accordance with Article 1, in which it is stated that "no other lights which may be mistaken for the prescribed lights shall be exhibited," the Guild would point out that in frequent cases the visibility of the side lights is much depreciated by the brilliancy of other lights placed in their vicinity, and another cause of unnecessary confusion is the shading over of lighted ports with red or green curtains.

In conclusion I am to state that the above points being of vital importance to the profession at large, the Guild earnestly hope that mention may be made of them in the report of the Committee.

I have, &c.

T. W. Moore,
Assistant Secretary.

The Chairman,
Side Lights Committee.

---

No. 3.—Further Letter from the Merchant Service Guild.

22, Canning Place, Liverpool,
19th June 1895.

Sir,

With reference to your Secretary's letter of the 30th ult., I am directed to state the Guild can only esteem it as a favour that they should be invited to address a further communication to you on this subject, and gladly avail themselves of the opportunity.

Whilst adhering to and confirming their previously expressed opinions as to the advisability or otherwise of the change which has been made in the mode of screening, the Guild think that the chief and most serious question which has now to be considered is, as to what will be the position of a British ship in case of collision under any circumstances with a foreigner. In such a case there can be no doubt whatever, but that every advantage will be taken by the latter of the fact, that the British ships' lights are not fixed in accordance with the practice of any other nation. The result will undoubtedly be endless litigation, and eventual injury to British shipping and the interests of the captains and officers.

They would, therefore, most respectfully suggest—

That the regulations as to screening and fixing of ships' side lights be made *international*, or,

That the Order in Council, of the 30th Jan. 1893, be rescinded, and the *status quo ante* re-established.

Further, I am desired to state they consider it of the utmost importance that the mode of carrying out the international rules of the road at sea should be absolutely uniform, especially with regard to fixing the lights, and they trust that your Committee may be pleased to take a favourable view of their representations.

I have, &c.

W. Moore,
Assistant Secretary.

The Chairman, Side Lights Committee.

App. 18.

# APPENDIX No. 18.

*Papers handed in by the Chairman.*

CORRESPONDENCE as to the ANGLE of SCREENING prior to 1892.

Side Lights Committee, Board of Trade,
18th May 1895.

I AM desired by the Committee on the Screening of Ships' Side Lights to ask whether you would be good enough to furnish them with information as to the manner in which your steamships were screened prior to the issue of the instructions requiring all vessels to be screened to 4°.

The points upon which the Committee would be glad to have returns are—

1. In what ships were the screens altered in consequence of the new instructions?
2. In which of these ships were the chocks cut down?
3. In which were the chocks deepened?

You will, I am sure, recognise that it is important that the information should be as accurate as possible.

I am, &c.
C. HIPWOOD,
Secretary.

---

Thos. Wilson, Sons & Co., Limited, Hull,
SIR, 21st May 1895.

IN reply to your letter of the 18th instant, respecting the screening of our steamers' side lights, we beg to inform you that all our steamers' side screens, prior to the issue of instructions requiring all vessels to be screened to 4°, were placed in a line with the ship's keel, in accordance with the Board of Trade rules.

The following steamers' screens have been altered by the Board of Trade in consequence of the new instructions:—

| | | |
|---|---|---|
| "Como" | "Montebello" | Chocks cut down ½ inch to ¾ inch. |
| "Domino" | "Plato" | |
| "Eldorado" | "Rollo" | |
| "Fido" | "Romeo" | |
| "Gozo" | "Tasso" | |
| "Hidalgo" | "Juno" | |
| "Milo" | | |

The under-mentioned have had their chocks deepened ½ inch to ¾ inch:—

"Argo" "Colorado."

Yours, &c.
JAMES RUTTER,
Marine Superintendent.

---

"Allan" Line and "State" Line of Steamers,
25, Bothwell Street, Glasgow,
DEAR SIR, 25th May 1895.

WITH reference to your circular letter of the 18th instant, prior to the issue of the Board of Trade regulations in 1892, our steamers were aimed at being screened in a parallel line with the keel, and when the new regulations came into force the screens of every steamer in the Line had to be altered with the exception of two.

As regards the alteration of the chocks, we are sorry we cannot give you the information you require, as our superintendent did not keep a note of the details of the alterations; all that he concerned himself with being to see that the necessary alterations were made to make the lights conform to the new rules. Our impression, however, is that in most of the ships the chocks would be cut down, but not deepened.

Yours, &c.
JAMES and ALEXANDER ALLAN,
per J. Smith Park.

---

British India Steam Navigation Company, Limited,
9, Throgmorton Avenue, London, E.C.,
SIR, 25th May 1895.

I HAVE the honour to acknowledge receipt of your letter of the 18th instant, and to inform you in reply that the following vessels belonging to the company have had their side-light screens altered in London in consequence of the new instructions, viz., "Africa," "Dunera," "Ethiopia," "Goorkha," "Golconda," "Java," "Manora," "Mecca," "Madura," and "Rewa."

In every case the chocks were cut down, and in no case were they deepened.

The other vessels owned by the company are trading on the coast of India, and I have no information on this point regarding them, but if you desire it I shall be glad to write to the managing agents of the company in India for the information.

I am, &c.
R. W. ARMOUR,
Joint Secretary.

---

Peninsular and Oriental Steam
Navigation Company,
122, Leadenhall Street,
London, E.C.,
SIR, 28th May 1895.

IN reply to your circular letter of the 18th instant, I am desired to enclose a diagram for your information, showing that 60 per cent. of the side lights in this company's steamers have been altered, 40 per cent. so as to bring the rays of the lights out as per AA, and 20 per cent. to bring the rays in or nearer to each other, as per CC. BB is the true 4 degrees angle.

I am, &c.
A. TAIT, Secretary.

---

The Cunard Steamship Company, Limited,
Liverpool, 29th May 1895.

SIR,

I BEG to enclose, for the information of the Committee, a list of the Cunard Company's steamers, the screens of which have been altered at the demand of the surveyors to the Board of Trade, and also a list of those of the company's steamers the screens of which have always been, and still remain, parallel to the middle line; the tracings show how, in a few of the vessels, the alterations were made, and if the Committee desire tracings showing how the screens were altered in some of the other vessels, the company will be glad to forward them.

I am, &c.
WM. WATSON,
General Superintendent.

---

LIST of the CUNARD COMPANY'S steamers, the Screens of which are parallel to the Middle Line.

| | |
|---|---|
| "Samaria." | "Morocco." |
| "Atlas." | "Trinidad." |
| "Marathon." | "Palmyra." |
| "Tarifa." | "Cherbourg." |
| "Kedar." | "British Queen." |

WM. WATSON,
Liverpool, General Superintendent.
29th May 1895.

---

LIST of the CUNARD COMPANY'S steamers, with the alterations made at the demand of the Surveyors to the Board of Trade.

"Cephalonia," chock on screen altered (*see* Tracing), May 1893.
"Aleppo," June 1893.
"Bothnia," June 1893.
"Servia," July 1893.
"Catalonia," July 1893.
"Skirmisher," July 1893.
"Aurania," wood face trimmed (*see* Tracing), July 1893.
"Gallia," screen bent inboard (*see* Tracing), August 1893.
"Etruria," screen bent inboard (*see* Tracing), September 1893,

"Umbria," screen bent inboard (*see* Tracing), September 1893.
"Pavonia" (*see* tracing). September 1893.
"Campania." Passed by Board of Trade in Glasgow.
"Lucania." Do. do.
"Sylvania." Do. do.

Wm. Watson,
General Superintendent.

Liverpool,
29th May 1895.

30, Jamaica, Glasgow,
26th June 1895.

App. 18.

Sir,

We have duly received your favour of 25th instant. All the information asked for in your letter of 18th May must be in the possession of the Board of Trade surveyors, who are in a better position to furnish what is required than we are.

We are, &c.
G. and J. Burns.

Note.—See also letter from the Pacific Steam Navigation Company, page 269.

## APPENDIX No. 19.

*Papers handed in by the Chairman.*

App. 19.

Letters giving the Opinions of Shipowners on the Question of Screening.

Side Lights Committee, Board of Trade,
25th June 1895.

I am directed by the Committee on Side Lights to state that it will be of great assistance to them if you will be good enough—

1. To inform them whether or not you approve of the present rule which requires side lights to be screened to 4° from the outside edge of the wick, with the reasons, so far as you will be good enough to state them, for your approval or disapproval:

2. If you do not approve of the present rule, to state the angle to which you consider side lights should be screened, and whether this angle should be calculated from the outside, middle, or inside of the wick, or in any other way.

I am, &c.
C. Hipwood,
Secretary.

---

Thos. Wilson, Sons, & Company, Limited,
Hull, 26th June 1895.

Sir,

In reply to your letter of the 25th instant we beg to inform you the whole of our fleet of steamships, having had their side lights screened to the 4° angle from the outer edge of the wick, by the Board of Trade staff here, we are quite satisfied with the present arrangement, and see no reason to make any further alteration.

Yours, &c.
James Rutter,
Marine Superintendent.

---

12, John Street, Sunderland,
26th June 1895.

Sir,

In reply to your communication of yesterday's date my marine surveyors inform me they do not think the present arrangement of the 10 point bearing could be improved upon.

The seafaring men whom I have consulted feel very strongly against any alteration from the present arrangement of the side lights.

I am, &c.
James Westoll.

---

Greenock, 26th June 1895.

Dear Sir,

We have your circular of yesterday. In our opinion for all practical purposes it is better to place side light screens parallel with the ship's keel and fasten on the ends of the screens a batten, in thickness equal to the distance from the face of the screens to the inner edges of the lenses of the lamps.

Yours, &c.
A. & J. H. Carmichael & Co.

---

Wm. Johnston and Company, Limited,
Liverpool, June 26th, 1895.

Dear Sir,

We are in receipt of your communication of the 25th inst. and beg to inform you we are most strongly opposed to the new rule which requires side lights to be screened to 4° degrees from the outside edge of the wick, our belief being that the same may lead to serious collisions.

This opinion is unanimous throughout the commanders of our steamers as well as of our marine superintendents.

We would strongly urge reverting to the old rule, which has been found to work well in practice now for a long period.

We are, &c.
Wm. Johnston and Company, Limited.

---

Shipowners' Parliamentary Committee,
1, Whittington Avenue, London, E.C.,
26th June 1896.

Sir,

I beg to inform you that I have submitted your circular of yesterday, upon the subject of side lights, to the chairman of this Committee.

He, however, directs me to state in reply that the subject does not, in his opinion, fall within the proper scope of the work of this Committee, and therefore, he is not prepared to invite the Committee to express any opinion upon the subject.

I am, &c.
W. H. Cooke,
Secretary.

---

Andrew Weir and Company,
102, Hope Street, Glasgow,
26th June 1895.

Dear Sir,

In reply to your circular of yesterday's date, we have to inform you that we have not had a single complaint from any of our captains regarding side lights as they are at present.

Yours, &c.
A. Weir & Co.

---

Liverpool, 27th June 1895.

Sir,

In response to your circular letter of the 25th inst., we have to say—

1. That we entirely disagree to the present 4° angle from the outside edge of the wick.

2. We are strongly in favour of the original angle of 2° from the middle of the wick.

We may add that all our senior and junior captains (numbering 16), as well as our certificated officers, are of the same opinion, and further that the assumed "dark lane" is a myth.

Yours, &c.
James Moss & Co.
Managers of the Moss Steamship Co., Limited.

---

Mersey Chambers, Liverpool,
27th June 1895.

Sir,

In reply to your communication of 25th inst. we beg to say—

1. That we strongly disapprove of the rule which requires the side lights to be screened to 4° from the outside edge of the wick as it is misleading, and renders it possible for them to be seen too far across either bow.

2. We consider the side lights should be screened on a line parallel to the keel of the vessel, measured from the outside edge of the wick.

We are, &c.
Thos. and Jas. Harrison.

---

APP. 19.

Peninsular and Oriental Steam Navigation Co.,
122, Leadenhall Street,
London, E.C.,
27th June 1895.

SIR,

IN reply to your favour of 25th inst., we beg to say that we do not approve of a hard and fast rule, which requires "side lights to be screened 4° from the "outside edge of the wick," for the reasons advanced through Admiral Wharton, by the late Committee that sat on this matter, *seq.*—

> "At the same time, we desire to point out that no strict uniformity of the angle at which the full strength of the lights is, in practice, visible, is possible, so long as a great variety of lamps are in use, and in view of this fact, as well as of the great improvements which have been, and are being made in the construction of lamps, and in the power of illuminants, and in the great increase in the size and speed of ships, we think that the Board of Trade should, in certain cases, have power to allow the angle of screening, upon the request of the shipowner, to be reduced to 3°, or even in cases of very long ships, to 2°."

An unvarying rule of screening at a fixed angle, cannot, in our opinion, be applied to all classes of ships (at the same time, in saying this, we desire to speak without prejudice, until the results of your investigation, which will doubtless exhaust the subject, are made public) we are impressed with the idea, the finer the angle of screening the greater should be the immunity from danger in general.

I am, &c.
F. R. KENDALL,
For the Managing Directors.

---

Baltic, Continental, and Portuguese
Steamship Offices,
Commercial Road, Hull,
27th June 1895.

DEAR SIR,

IN reply to your circular of 25th inst., *re* side lights, we beg to state that we are quite satisfied with the rules applicable at present.

Yours, &c.
For BAILEY and LEETHAM,
H. S. KIRKUS.

---

The Angier Steam Shipping Company, Limited,
118, Bishopsgate Street, Within, E.C.,
London, 28th June 1895.

DEAR SIR,

IN reply to your inquiry, our experience from sea voyages in our own boats and observations, we unhesitatingly are of opinion that the lights should be placed so as not to cross the bows at any point ahead.

Yours, &c.
For ANGIER BROTHERS,
C. B.

---

The Greenock Steamship Company, Limited,
Greenock, 28th June 1895.

SIR,

IN reply to circular of 25th inst. issued by the Committee on Side Lights, I have now the pleasure to submit answers to the queries which I hope will be found useful to the Committee when dealing with this most important subject:—

First.—I do not approve of the 4° angle because the lights placed at this angle would cross each other at a relatively greater distance ahead of the broad vessel as compared with vessels of narrower beam increasing considerably the range of dark lane which it is of the utmost importance should be avoided.

Second.—The angle should be taken from the centre of the wick because the rays of light diverging from the centre would be a more reliable point to take the angle from, than from either the outer or inner edge of the wick, as the wick is not always properly trimmed, consequently the flame is not always of uniform intensity.

The above replies have been very carefully considered in conjunction with Captain George J. Allan, Marine Superintendent of the Greenock Steamship Company, Limited, under my management, and, at his request, I have pleasure in adding that from his experience he is convinced that if side lights were placed within a reasonable distance from each other (the closer the better) and the lights to show from direct ahead to two points abaft the beam less confusion would result. The angles of the lights on several of our steamers have been repeatedly altered to satisfy the views of different surveyors.

I am, &c.
D. MACDOUGALL.

---

57, Gracechurch Street, London, E.C.
28th June 1895.

SIR,

IN reply to your letter of the 25th inst. we have to inform you that we do not approve of the present rule which requires side lights to be screened to 4° from the outside of the wick.

We are of opinion that the side lights of any ship should be screened on a line with the keel, and so that the rays of either light should show as little across the bows as possible.

We are, &c.
JOHN FENWICK & SON.

---

Glasgow, 28th June 1895.

SIR,

WITH further reference to your letter of the 25th inst. we have given considerable attention to the subject of screening of side lights, and we have also discussed the matter with many of our masters and officers since the question first came so prominently before the public, and in reply to your inquiry—

1. We do not approve of the present rule which requires side lights to be screened to an angle of 4° inwards from the line of keel.

We do not approve of any system of screening by which the "direct rays" of the red light are visible from the starboard side of the line of keel projected ahead, or the "direct rays" of the green light from the port side of the line of keel projected ahead.

All the masters and officers we have consulted on this point deny the existence in practice of any dark lane ahead of a ship, and this is confirmed by a member of our firm who has had considerable nautical experience. Geometrically such a lane may be traced, practically it does not exist as the course of a ship cannot be kept mathematically straight, and even under the most favourable conditions of sea, wind, and careful steering, a ship's head is continually moving from one side to the other showing either one or the other or both of the side lights; in addition to this while the "direct rays" of any light screened from the outside edge of the wick in a line parallel to the keel of the vessel may be theoretically cut off from the vision of any person on the other side of the line of screen projected ahead yet the divergent rectilinear rays, which emanate from the lens of a side light, are seen beyond such direct line, and it seems to be a well recognised experience among officers at sea that while their line of vision is crossing the theoretical dark lane the divergent rays or "loom" as above described are always seen during such brief interval.

2. We are of opinion that side lights of vessels should be screened in a line strictly parallel with the keel measured from the outer edge of the wick, but as the "burners" or "wickholders" are frequently made flat this would lead, if fixed in the lamp "fore and aft" instead of "athwart-ship," to the direct rays of the light not being visible up to the line of the keel, and we would suggest therefore that the "burners" should be circular and the measurement taken from the outside of the wick.

We have, &c.
CAYZER, IRVINE, & Co.

---

Glasgow, 1st July 1895.

SIR,

WITH further reference to our letter of the 28th ult. we find that a clerical error was contained in that letter, and we would be glad if you take a note of the change.

The last two lines of the letter should have read: "taken from the middle of the wick."

We have, &c.
CAYZER, IRVINE, & Co.

Pacific Steam Navigation Company,
Liverpool, 28th June 1895.

Sir,

We have to acknowledge the receipt of your letter dated 25th instant, and in reply to the inquiry as to the manner in which the steamers of this Company were screened prior to the issue of the instructions requiring all vessels to be screened to 4°, have simply to state that the screening of the lights was to the order of the Board of Trade surveyors in every case which we presumed to have been in order.

In reply to Questions 1, 2, and 3 in your letter of 18th instant, viz.:—

In what ships were the screens altered in consequence of the new instructions?

In which of these ships were the chocks cut down; and

In which were the chocks deepened?

We have to say that the screens were altered in the four steamers of the Company running in the Orient Line between London and Australia, viz., "Orizaba," "Oroya," "Orotava," and "Oruba," and in the following steamers of the Liverpool and Valparaiso Mail Line, viz., "Iberia," "Liguria," "Potosi," "Britannia," "Sorata," and "Galicia"; that the screens were shortened and chocks cut down in all the steamers, and that in none of them were the chocks deepened.

With reference to your further letter dated 25th instant we have to state that we do not approve of the present rule which requires side lights to be screened to 4° from outside edge of wick, as we consider such screening attended with danger, as these lights can be seen at one time in different positions of the ship. This previously meant the approaching ship coming straight towards you, whereas now it does not, and consequently the rules of the road in practice for such a long time may become a positive danger if followed out. Under separate cover we send you a diagram illustrative of this.

As we do not approve of the present rule we beg to state in answer to Query No. 2 in the same letter, that we consider the angle of screening should never exceed 1° outside of the wick, that the crossing of the rays should under no circumstances be under 5 cables length from the bow, that there should be two sizes of standard side and masthead lights, one for vessels that steam up to nine knots, the other of the highest power and best lenses for steamers of higher speed, and finally, that there should be absolute uniformity in colour and position of side lights.

Yours, &c.
Henry Ward.

---

"Australasian" Line of Packets,
25, Water Street, Liverpool,
29th June 1895.

Dear Sir,

In reply to your circular letter of the 25th inst. the side lights should be screened to 4° from the centre of the wick, so that there will be no dark lane ahead of the ship between the two lights; but certainly not to have the lights to show on the other bow.

Yours, &c.
Gracie, Beazley, & Co.

---

The Shipping Federation, Limited,
101, Leadenhall Street, London, E.C.,
29th June 1895.

Sir,

I have to acknowledge your circular letter of the 25th instant regarding the screening of side lights, which matter does not come within the scope of the Federation rules, and my executive are therefore not prepared to express any corporate opinion on the subject.

I may, however, say that some of our association members are deeply interested in the matter; and—

(1.) None of them who have expressed opinions on the subject approve of the present rule, which requires side lights to be screened to 4° from the outside edge of the wick, and for the reason that such screening causes the direct rays of light to cross the bows in contravention of the articles.

(2.) They consider that the side lights should be screened in strict accordance with the Order in Council of August 1884, by adhering to the arc of 10 points, starting from two points abaft the beam, so as to allow the direct rays of light to be seen right ahead, on a line drawn parallel with the keel at the lamp station on either side, touching the inner edge of the lens, as there may be no wick in some cases.

I am, &c.
G. A. Laws,
General Manager.

---

Royal Mail Steam Packet Company,
18, Moorgate Street, London,
1st July 1895.

Sir,

I am desired to acknowledge the receipt of your letter of the 25th ult., and in reply to say that—

(1.) This company do not approve of the present rule which requires side lights to be screened to 4° from the outside edge of the wick, because when so screened the rays are seen across the opposite bow at an angle which will require two ships approaching each other on nearly parallel courses to act under different articles of the regulations for preventing collisions at sea, when, by keeping their original courses they would pass clear of each other, and if meeting under similar conditions in daylight they would not alter their course at all.

(2.) The company consider that the side lights should be screened to show as little as possible across the bow, but we do not think it would be prudent to reduce this beyond the angle produced by screening the light straight ahead parallel to the keel from the inside edge of the wick, thus allowing the whole of the wick to be seen right ahead of the light, and the rays from the outside edges to cross at a considerable distance ahead of the ship.

I am, &c.
J. A. Barrett,
Assistant Secretary.

---

Shaw, Savill, and Albion Company, Limited,
34, Leadenhall Street, London,
2nd July 1895.

Sir,

In reply to your circular of 25th June we beg to state—

1. (*a.*) We do not approve of any arrangement of side lights which will permit of the lights intersecting each other at any angle whatever.

(*b.*) Our chief reason is that it is essential that the master of a vessel should know at the earliest possible moment when he has crossed the bow of an approaching vessel, and that there should never at any time be the possibility of doubt as to which bow of the approaching vessel is presented to him.

2. We think the lights should be so placed as to describe an arc extending from right ahead of the light, parallel with the keel, to two points abaft the ship's beam. It is suggested that side lights so placed leave a "dark lane" between them, but we have not found that such lane has any practical existence. Even if such dark lane did exist it would form a less source of danger and perplexity than would arise when the lights of an approaching vessel cross each other in front of her track.

We are, &c.
J. A. Potter,
Shaw, Savill, and Albion Co., Limited.
Manager.

---

1, India Buildings, Liverpool,
2nd July 1895.

Sir,

I have to thank you for your letter of 25th ultimo.

I consider that side lights screened under the present rule answer their purpose with sufficient practical accuracy, but as this purpose was, in my judgment, equally well served by the previous regulation, which I understand to be that adopted by other maritime nations, I regret that the present regulation has been enforced.

Yours, &c.
Alfred Holt, Manager,
Ocean Steamship Company.

---

Liverpool, 2nd July 1895.

Sir,

In reply to your letter of the 25th ultimo, we have to state that we disapprove of the present rule requiring side lights to be screened to 4° from the outside edge of the wick.

App. 19.

Our reasons for this disapproval are —

(1.) That when the side lights are so screened it is impossible for vessels to be correctly aware of the relative positions of one to another, or what course to take when the two lights can be seen across the bow of the ship.

(2.) That there is no international agreement with other countries for side lights to be similarly screened.

We consider that the old rule whereby side lights were to be screened from the inside of the wick to the outside of the chock on the screen, and parallel to the keel of the ship provided in the best possible way for preventing collision at sea.

We are, &c.
LAMPORT AND HOLT.

---

23, Market Street, Aberdeen,
SIR, 2nd July 1895.

I DULY received your letter of 25th ultimo, and am directed by my association to say that they disapprove of the side lights being screened as at present because the rays cross too close to the bow of the vessel, and make it difficult to keep a proper lookout from the forecastle head.

The members of my association are not experts, and I am unable to state to you how the angle for screening should be calculated, but they are of opinion that the converging rays should cross not less than two ship lengths ahead of a vessel's bow.

I am, &c.
L. MACKINNON, Secretary,
The Aberdeen Shipowners' Association.

---

Clyde Shipping Company, Limited,
21, Carlton Place, Glasgow,
DEAR SIR, 2nd July 1895.

IN reply to your circular letter of 25th ultimo, in regard to screening of side lights, we have to say that we do not approve of the present regulations issued and carried out by the Board of Trade at so much expense for alterations to ourselves and other shipowners.

We considered that the side lights were much better placed on the old system, and gave every satisfaction, and so far as we have ever learned were perfectly safe for navigation.

We considered that the new system of 4° lends itself to confusion more so than the old system.

The old system of screening side lights when parallel with keel gave an angle of 2° over the bow, and so long as this was obtained it was immaterial how it was measured.

Yours, &c.
J. CUTHBERT.

---

Asiatic Steam Navigation Company, Limited,
SIR, Liverpool, 3rd July 1895.

IN reply to your letter of the 25th June, we have the honour to state—

1. That we disapprove of the rule quoted in your paragraph 1, and for the following reasons, viz. :—

(A.) The arc within which, under this rule, both lights are seen, is so extended beyond that which obtains under the old rule as to considerably and dangerously increase the difficulty which necessarily arises when vessels meet by night, nearly or quite "end on," of ascertaining on board each ship the relative position and course of the other.

(B.) This rule has not been adopted by other nations, and no international agreement exists for its general adoption.

2. That we consider that the old rule, whereby side lights are to be screened, so that a line drawn from the inside of the wick to the outer edge of the chock at end of the screen shall be parallel to the keel is for all practical purposes satisfactory.

B. We are confident that where this rule is followed, and ordinarily careful seamanship is shown, the risk of collision is reduced to a minimum.

Yours, &c.
TURNER AND COMPANY,
Managers.

---

The Hartlepools Shipowners' Society,
SIR, West Hartlepool, 3rd July 1895.

YOUR letter of the 25th ultimo was this morning duly considered at a meeting of members of the above Society, and I am directed to state in reply, that in the opinion of the Society there existed no valid reason for the recent alteration in the shading of side lights.

The Society is of opinion that the record as to collisions, especially as to steamers, is an exceedingly light one, and cannot reasonably be expected to be much lessened.

I am, &c.
F. YEOMAN,
Secretary.

---

20, Water Street, Liverpool,
SIR, July 3rd, 1895.

IN reply to your favour of the 25th ultimo, we beg to state that we entirely disapprove of the rule requiring side lights to be screened to 4° from the outside edge of the wick.

The reasons for which we object to the said rule are (1) that it is not adopted by the mercantile marine of other countries, and (2) we consider it most difficult for vessels to correctly judge each other's position when the two lights can be seen across the bows of the vessel. We consider the old style of screening side lights an infinitely preferable and safer one, *i.e.*, where the lights are screened from the inside of the wick to the outside of the chock on the screen.

We remain, &c.
JOHN GLYNN AND SON.

---

The Clyde Steam Shipowners' Association,
24, George Square, Glasgow,
SIR, 3rd July 1895.

REFERRING to your circular letter of the 25th ultimo my directors desire me to say that a number of the leading members of this Association have received similar circulars and are going into the question with their superintendents with the view of writing to you direct. In these circumstances my directors do not deem it advisable to reply to your questions in the collective name of the Association.

I am, &c.
NEILSON BIRD,
Secretary.

---

19, Tower Buildings North, Liverpool,
SIR, 3rd July 1895.

IN reply to your letter of the 25th ultimo, we have to state that we disapprove of the present rule requiring side lights to be screened to 4° from the outside edge of the wick.

Our reason for this disapproval are—

(1st.) That when the side lights are so screened it is impossible for vessels to be correctly aware of the relative positions of one another or what course to take when the two lights can be seen across the bow of the ship.

(2nd.) That there is no international agreement with other countries for side lights to be similarly screened.

We consider that the old rule whereby side lights were to be screened from the *inside* of the wick to the outside of the chock on the screen and parallel to the keel of the ship provided in the best possible way for preventing collision at sea.

We are, &c.
ROBERT ALEXANDER & Co.

---

Shipowners' Association,
6, Water Street, Liverpool,
DEAR SIR, 3rd July 1895.

YOUR circular letter of the 25th June has been laid before the Committee of this Association by whom we are directed to say that they do not approve of the rule which requires side lights to be screened 4° from the outside edge of the wick on the grounds—

(1.) That when so screened the two side lights can be seen across the bow of the ship; and

(2.) That there is no international agreement with other countries providing for the international adoption of this rule.

In their opinion side lights should be screened in accordance with the Order in Council of August 1884 and the practice which has obtained for years, and that the angle should be calculated from the inside of the wick.

We are, &c.
WEIGHTMAN, PEDDER, & Co.
Secretaries.

27 and 29, James Street, Liverpool,
SIR, 4th July 1895.

REPLYING to your letter of the 25th ult., after going carefully into the matter with our captains, we have come to the conclusion that we must disapprove of the present rule requiring side lights to be screened to 4° from the outside edge of the wick.

And the reasons for our disapproval are—

1. That when the side lights are so screened it is impossible for vessels to be correctly aware of the relative positions of one to another or what course to take when the two lights can be seen across the bow of the ship.
2. That there is no international agreement with other countries for side lights to be similarly screened.

We consider that the old rule whereby side lights were to be screened from the inside of the wick to the outside of the chock on the screen and parallel to the keel of the ship provided in the best possible way for preventing collision at sea.

We are, &c.,
For FREDK. LEYLAND & Co., Limited.
M. MCMURPHY,
Manager.

---

"Anchor" Line,
45 to 57, Union Street, Glasgow,
SIR, 4th July 1895.

IN reply to your communication of 25th ult., we have to state that we do not approve of the present rule which requires side lights to be screened to 4° from the outside edge of the wick, as it has the effect of showing the lights across the bows.

We were perfectly satisfied with the system that existed previous to the application of the new rule, and we are not aware that it was found in practice to be in any way objectionable.

We are, &c.
HENDERSON BROTHERS.

---

SIR, Liverpool, 5th July 1895.

IN reply to your letter of the 25th ult., we have to state that we disapprove of the present rule requiring side lights to be screened to 4° from the outside edge of the wick.

Our reasons for this disapproval are: (1) that when the side lights are so screened it is impossible for vessels to be correctly aware of the relative positions of one to another, or what course to take when the two lights can be seen across the bow of the ship; (2) that there is no international agreement with other countries for side lights to be similarly screened.

We consider that the old rule whereby side lights were to be screened from the inside of the wick to the outside of the chock on the screen and parallel to the keel of the ship provided in the best possible way for preventing collisions at sea.

We are, &c.
HAMILTON, FRASER, & Co.

---

The Cunard Steamship Company, Limited,
Secretary's Office, Liverpool,
SIR, 8th July 1895.

REPLYING to your letter of the 25th ult.—

1. We disapprove of the present rule which requires side lights to be screened to 4° from the edge of the wick, for the following reasons:—
   (1.) It is contrary to the international regulations.
   (2.) When lights are so screened it is impossible for a vessel seeing both side lights of an approaching vessel to tell within 8° of the course she is steering, thus causing uncertainty and risk of collision.
2. The international rule we consider the best possible safeguard against collisions at sea.

The above is the unanimous opinion of our commanders and officers.

I am, &c.
T. MOORHOUSE,
Secretary.

---

Mersey Chambers, Liverpool,
SIR, 9th July 1895.

REPLYING to your favour of 25th ult., we strongly disapprove of the present rule requiring the side lights to be screened to 4° from the outer edge of the wick.

Because—

(1.) Where the side lights are so screened it is impossible for vessels to judge correctly their relative positions one to another, or what course to take when both lights are seen across the bow. APP. 19.

(2.) There is no international agreement for side lights to be so screened.

We consider that the old rule whereby side lights were screened from the inside of the wick to the outside of the chock on the screen and parallel to the keel of the ship provided in the best way for preventing collisions at sea; and as uniformity of practice and position is all-important, we suggest that Government should endeavour to get an international agreement on this point, instead of insisting on the present 4° rule, which nearly all competent and practical maritime authorities condemn.

We are, &c.
For the BEDOUIN STEAM NAVIGATION COMPANY, LIMITED.
W. AND R. THOMSON,
Managers.

---

British India Steam Navigation Company, Limited,
9, Throgmorton Avenue, London,
SIR, 9th July 1895.

I DULY received your letter of the 25th ult., and have the honour to reply as follows to the inquiries made—

(1.) We do not approve of the present arrangement of screening side lights to 4° from the outside edge of the wick principally for the following reasons—

(*a.*) An approaching ship might not be able to tell in sighting three lights how she is relatively situated to the one she is meeting.

(*b.*) We prefer to have our side lights at the sides of the bridge in order that they may be continually under the eye of the officer of the watch. The present arrangement makes it often impossible to do so on account of obstructions in the way, and in such cases it is necessary in order to comply with the law to fit the lights forward where they are removed from the observation of the officer on the bridge.

(2.) We consider that the lights should be screened to the line of the keel. This would obviate any mistake on the part of an approaching ship and would, in most cases, make it possible for the lights to be fixed on the sides of the bridge.

I am, &c.
R. W. ARMOUR,
Joint Secretary.

---

80, Buchanan Street, Glasgow,
SIR, 11th July 1895.

WE duly received your letter of 25th ult. containing questions put by the Committee on Side Lights and as we presume that the Committee would prefer to have opinions from experienced men, we sent copies of these questions to two of our shipmasters and herewith you have their replies.

Captains Pattman and Radford are men of ability and experience and we hope that their opinions will be of value to the Committee.

We are, &c.
AITKEN, LILBURN, AND COMPANY.

---

Ship "Loch Broom,"
S.W. India Dock, London,
GENTLEMEN, 2nd July 1895.

WITH reference to your letter of 28th June concerning side lights I have thought over very carefully my experience in the English Channel and elsewhere, and have come to this conclusion.

No. 1. I do not approve of the 4° angle of crossing from the outside of the wick for the following reason. Bearing in mind sections (*b*), (*c*), and (*d*) Art. 2 of the regulations which set out that side lights shall be fixed so as to throw the lights from right ahead to two points abaft the beam (10 points in all) and screened so as to prevent the lights from being seen across the bow, and I believe it is in the interest of safe navigation to narrow the field in which the two lights may be seen together as much as possible.

No. 2. In my opinion the lights should be screened in a fore and aft line the points to calculate from being

App. 19.

the middle of the wick or flame and the outer edge of the screen chock. I have no doubt this arrangement will give ample if not full show of the lights right ahead.

I am, &c.
JOSEPH RADFORD,
Master.

Messrs. Aitken, Lilburn, and Company, Glasgow.

---

Ship "Loch Torridon,"
S.W. India Dock, London,
2nd July 1895.

GENTLEMEN,

IN accordance with your wish I herewith send you my replies to the questions you received from the Side Lights Committee. In reply to question No. 1, I am in favour of the regulations in force prior to January 1892. The lights being so screened as to show the light right ahead, giving in theory a so-called "dark lane" which in practice did not exist. The present system of screening lights allows them to converge at calculated distances of from 70 to 500 feet ahead of the screens and which shows according to nautical ideas across the bows. Especially in rivers and narrow waters is this a source of great and serious danger to safe navigation, besides placing a British ship, in case of collision with a foreign ship, at a great disadvantage in the Admiralty Courts, as the rule enforced since January 1892 is not an international rule or law.

In reply to question No. 2. I consider that my reply to No. 1 replies to this also. That is the rule or regulations in force prior to January 1892 should be again adopted.

I remain, &c.
R. PATTMAN,
Master.

Messrs. Aitken, Lilburn, and Company, 80, Buchanan Street, Glasgow.

---

Glasgow Shipowners' Association,
30, Gordon Street, Glasgow,
11th July 1895.

SIR,

I WAS duly favoured with your circular letter of the 25th ult., containing the two queries put by your Committee *re* side lights.

I enclose copy of one reply which I have received to the circular, which I issued to the leading firms who are members of this Association, but I understand that Messrs. Cayzer, Irvine, and Co., Messrs. Henderson Brothers, and Messrs. James and Alexander Allan have been in direct communication with you on the subject.

I shall write again should I receive any further communications on the subject.

I am, &c.
J. MUIRHEAD,
Secretary.

*Copy letter referred to.*

Glasgow, 8th July 1895.

DEAR SIR,

IN answer to your letter of the 1st inst. *re* the screening of sidelights, I must say that I do not approve of the present rule which requires side lights to be screened from the outside edge of the wick so that the rays shall cross the line of the ship's keel.

To see both side lights at the same time must be embarrassing to masters and pilots in narrow waters, especially when steamers and sailing vessels get into close quarters, in which case it would be easy to mistake the red light of a steamer and the green light of a sailing ship for the lights of one steamer.

I consider that the side lights should be screened so as to show in a straight line with the ship's keel from the inside edge of the wick, and prevent them being seen across the bow.

Yours, &c.

The Secretary,
Glasgow Shipowners' Association.

---

19 and 20, Chapel Chambers North,
28, Chapel Street, Liverpool,
13th July 1895.

SIR,

IN reply to your letter of the 25th ult., we beg to state that we disapprove of the present rule requiring side lights to be screened to 4° from the outside edge of the wick.

We disapprove, because when so screened it is impossible for vessels to be correctly aware of the relative positions of one to another, or which course to take when the two lights can be seen across the bow of the ship, and there is no international agreement with other nations for side lights to be similarly screened.

In our opinion the old rule, whereby side lights were to be screened from the *inside* of the wick to the outside of the chock on the screen and parallel to the keel of the ship provided in the best possible way for preventing collision at sea.

We are, &c.
STRONG, REID, AND PAGE.

---

Waterford Steamship Company, Limited,
Waterford, 15th July 1895.

SIR,

IN reply to your letter of 25th ult., we have to state that in our opinion the lights should be so screened that the outside edge of the wick and outside of the chock would be in line and parallel with the line of the keel; this is the only way in which the international regulations could be observed, and the arc of visibility of the light kept to 10 points; screening to the inside edge of the wick would allow the light to show at an angle of about 2° across the bow, and would not accord with the international regulations.

I am, &c.
C. MORLEY,
Managing Director.

---

General Shipowners' Society, London,
1, Whittington Avenue,
Leadenhall Street, E.C.,
July 16th 1895.

SIR,

I HAVE to acknowledge the receipt of your circular letter of the 25th ult. regarding the screening of side lights which I have submitted to the Committee of this Society for their consideration.

In reply, I have to say—

(1.) My committee do not approve of the present rule which requires side lights to be screened to 4° from the outside edge of the wick for the reason that such screening allows so much light to cross the line of the ship's bow as to cause uncertainty as to the course which she is steering.

(2.) My committee consider that ordinary side lights should be screened to 0° of convergence from the inside edge of the wick, the position of the wick being fixed, and its width limited.

(N.B.—This screening would, with the present ordinary position and width of wick, give about 2° of convergence from outside edge of wick.)

I am, &c.
W. H. COOKE,
Secretary.

---

Palmerston Buildings, 93, Bishopsgate Street,
London, E.C., 17th July 1895.

DEAR SIR,

REFERRING to your letter of the 25th ultimo *re* side lights, we do not approve of the present rule which requires the side lights to be screened to 4° or any angle.

It seems to me the old rule was much better, *i.e.*, the side lights to run parallel with the line of vessel and show two points abaft the beam, because two ships meeting end on, or nearly so, can see at a glance what each are about to do, as the slightest deviation off their course on either side immediately closes in one light and opens out the other. The 4° angle keeps both lights open too long, and when seen that the course has been altered on one ship or the other, it is often too late to avoid colliding.

Yours, &c.
R. GORDON & Co.

---

Stockton Shipowners' Association,
Stockton-on-Tees,
19th July 1895.

SIR,

I HAVE to acknowledge the receipt of your valued favour dated the 25th ultimo *re* arrangement of side lights, and in reply am instructed to state that we agree that it is desirable that the lights should be screened from the outside edge of wick, but would suggest that they should be arranged to impinge at the point of extreme range of lights, say, 2 miles, instead of 4°, as required at present, which we consider too close for safety.

I am, &c.
E. ASTON,
Hon. Secretary.

"Allan" Line and "State" Line of Steamers,
25, Bothwell Street, Glasgow,
DEAR SIR, 22nd July 1895.

WE duly received your favour of 25th ult. *re* screening of side lights.

We have been in communication with a considerable number of our masters, and find their opinion is practically unanimous in condemnation of the present rule as being dangerous, and likely to lead to accidents.

Their opinion is that the 4° angle causes the lights to cross too near the bows of steamers, and makes it most difficult for vessels meeting to know whether the other is coming end on or not, and that, in narrow and crowded waters, the present screening is specially objectionable and conducive to danger. In some of the smaller and narrower vessels, too, the glare of the light shows across the forecastle deck in foggy weather and attracts the eye.

Our masters attach no practical importance whatever to the dark lane theory, although we think it only fair to say that we have not as yet heard of a case in practice in which difficulty has arisen from the lights being screened to the 4° angle.

Their opinion is also practically unanimous in recommending a reversion to the old practice of screening the lights so as to show in a line parallel with the keel from the inside of the wick to the outside of the chock of the screen (and, of course, two points abaft the beam), but possibly it might be better, instead of the inside of the wick, to adopt the centre of the burner, as in screwing in burners there is a tendency for these to adopt fore and aft or other positions. Care should also be taken that in screening the side lights the value of the lights be not impaired, and it may be worthy of consideration whether something should not be done to ensure greater uniformity in the shade of colour of the glass of side lights, as at present the green lights can sometimes hardly be distinguished from white.

We are strongly of opinion that even were the present method of screening unobjectionable in itself, it should be discountenanced and abandoned until an agreement were come to with other maritime countries to adopt it. The object to be attained in screening the side lights to the 4° angle is, as we understand it, to prevent the lane between the converging rays of the lights in which they are invisible or indistinctly seen extending too far ahead of the ship, and in our opinion it would be sufficient if both lights could be distinctly seen from either side of a vessel's bridge 350 yards ahead of the lights. It seems to us from Sir Digby Murray's experiments (pp. 36 and 37 of the Blue Book) that this would be attained by screening the lights to an angle of 3°, care being taken as to the quality of the lights, especially the green.

We are, &c.
JAMES and ALEX. ALLAN.

---

GENTLEMEN,

IN reply to your circular of the 25th June 1895 relating to our opinion on the side lights which has not been answered in consequence of writer's absence in whose department it is, we may say we feel it difficult to answer right off without more explanations than we can commit to writing.

First we see no objection to the present rule which requires the side lights to be screened to 4° from the outside of the wick, provided that the light does not exceed that angle; in providing for this the position of lights have to be taken to account, as in a steamer with a length of 400 feet, and the lights in the middle of the vessel of broad beam, the dark lane would not be the same as the same vessel with the side lights exhibited from the forecastle lighthouses 30 feet from the stem, and narrowed, say, in a fine pointed vessel probably 16 feet less than extreme beam than if placed amidships; then again, there is a great difference in the ordinary cargo boat with a bluff topgallant forecastle when in ballast to what she is when loaded; the vessel usually being a lot by the stem and the ship a lot of sheer, the light becomes obscured until the vessel has a broad sheer from a right ahead line, then if this vessel had the lights on the forecastle, the result of the placing of the lights at different places causes intense confusion; as in no two vessels do the lights intersect at the same distance from the vessel, the distance being controlled by the beam of the vessel the position placed in, the sheer and whether light or loaded.

Our opinion as to where the angle should be taken from of the wick; we opine that the 4° should be from the outside of the wick. There is a great deal depends on the reflector and the strength of the light; with a screen 3 feet long the distance at which the lights cut can easily be worked, and when 4° is used, or the old method of the wick just clearing the block at front of the screen. The great trouble is want of uniformity in placing the lights on vessels; our opinion is that they ought always to be placed in such position as the officer of the watch can have them under observation at all times, and that all lamps and burners ought to be examined and certified by an officer of the Board of Trade and that alterations should not be permitted to be made with the lights and screens after having been passed by an officer of the Board of Trade as it induces a sort of contempt for the experience of the officers when such differences arise at the various ports.

If writer has diverged from the direct answers required in your circular he could not even touch the question without such explanations and the experience of 55 years, even going before lights were in vogue at all right up to date as I have made lights a part of my study from their introduction.

For MOREL BROS. & Co.
OLIVER PHALP,
Marine Superintendent.

App. 19.

---

The Indo-China Steam Navigation Company,
Limited,
29, Cornhill, London, E.C.,
SIR, 24th July 1895.

I AM in receipt of your circular letter of 25th ult., and in accordance with your request for information, have passed your letter on to several of our captains now at home on leave, I beg to enclose their replies, which you will notice are unanimously in favour of a continuation of the present arrangements.

Yours, &c.
A. G. WELLS,
Secretary.

---

Avondhu, Grangemouth,
DEAR SIR, 2nd July 1895.

I RECEIVED your letter of yesterday, with the enclosed form, copy from the Side Lights Committee. In reply, I beg to state that I approve of the present rule for the side lights, as it is simple, and gives no trouble; I think, however, that the side lights of all steamers should be carried on the bridge, so that the officer of the watch can see that they are burning well, and not on the forecastle where the officer has to trust to a quarter-master, or the man on the lookout, to see they burn well.

I am, &c.
H. W. HOGG.

---

26, Gordon Street,
Gordon Square, W.C.,
SIR, 3rd July 1895.

IN accordance with your request, I beg leave to say the present angle of shade for side lights, viz., 4°, is in my opinion amply sufficient for all purposes.

I remain, &c.
FREDERICK DAVIS.

---

The Priory, Fortrose,
DEAR MR. CHEYNE, 22nd July 1895.

I HAVE been making inquiries *re* the proposed changes in side lights, and have come to the conclusion that the present rule, which requires side lights to be screened to 4° from the outside edge of the wick to be all sufficient.

I think that any change would be confusing for a very long time, and would very likely be the cause of a number of collisions before they were properly understood.

Yours, &c.
W. D. M. YOUNG.

---

App. 19.

Stoke Barton, Hartland, North Devon,
5th July 1895.

Dear Sir,

I received your letter of 1st instant yesterday.

I did not know that there was any idea afloat for the alteration of the screening of side lights until now, and quite fail to understand why any alteration should take place. I approve of the present rule, which requires side lights to be screened to 4° from the outside edge of the wick. I have known or heard of no difficulty or accident arising from the present system of screening, and, speaking from results, do not consider it necessary to alter it.

Yours, &c.
T. R. Galsworthy.

A. Cheyne, Esq.

---

The Irish Shipowners' Company, Limited,
113, Corporation Street,
Belfast, 31st July 1895.

Dear Sir,

Referring to your circular letter of the 25th June last—

1st. We do not approve of the side lights being screened as to show so much as 4° across the bow, and our chief reason for this is that, in the narrow excavated channels of our port here, or in the entrance to Baltimore Md., U.S.A., of which we have extensive experience, vessels passing have to pass each other very closely, and it requires a decided alteration in the vessel's course to shut in any one of the lights, and this in a place where it is possible to deviate very little from the straight course with safety.

2nd. We would suggest a compromise, say, of the light to be screened from 1° to 2° from the outside edge of the wick, and for this reason, our experience is that with the old method of screening the lights from right ahead that the lights lose considerably in their brilliancy when viewed from this position.

We are, &c.
Thos. Dixon and Sons.

---

North of England Freight, Demurrage,
and Defence Association,
Newcastle-upon-Tyne,
7th August 1895.

Dear Sir,

In reply to your circular letter of the 25th June, I beg to state that my committee consider that the side lights should be screened in accordance with the Order in Council of August 1884, having the arc of 10 points from two points abaft the beam. This has answered well in the past, and they are of opinion that the intended alteration will not be satisfactory.

Yours, &c.
Henry Miller,
Secretary.

---

Sunderland Shipowners' Society,
50, West Sunniside, Sunderland,
7th August 1895.

Sir,

Your circular letter, dated 25th June, was laid before my committee to-day, when I was instructed to inform you that having read a copy of the reply given by the General Shipowners' Society of London, this society fully endorses the objections raised therein and approves of the suggestion that ordinary side lights should be screened to 0° of convergence from the inside of the wick.

Yours, &c.
Chas. Booth,
Secretary.

---

North of England Steamship Owners' Association,
G, King Street, Quayside,
Newcastle-on-Tyne,
8th August 1895.

Sir,

In reference to your inquiry of 25th June last regarding the screening of side lights, my committee have carefully considered the subject, and have obtained the opinion of a number of nautical experts, who are unanimous in their opinion that the side lights should be screened in direct accordance with the Order in Council of August 1884, by adhering to the arc of 10 points, starting from two points abaft the beam, so as to allow the direct rays of light to be seen right ahead on a line drawn parallel with the keel at the lamp station on either side, touching the inner edge of the lens.

I am, &c.
John Morrison,
Secretary.

---

General Steam Navigation Company,
55, Great Tower Street, London, E.C.,
17th August 1895.

Sir,

Referring to your circular letter of the 25th June, I beg to hand you herewith a copy of our Marine Superintendent's report expressing his opinion (which, you will notice, he says is confirmed by the captains in our employ) that side lights should be fixed in accordance with the Order of the Council of August 1884, so as to allow the direct rays of the light to be seen from right ahead on a line with the keel of the vessel to two points abaft the beam.

Yours truly,
Charles H. Glyn.

---

(*Copy.*)

With reference to the attached letter from the "Side Lights Committee" "*re* screening of side lights," and upon which the directors request my opinion, with regard to both questions numbered 1 and 2, I beg to state that I do not approve of side lights being screened at any angle which would permit the lights being seen across the bow; as it would, in my opinion, increase rather than lessen the risks of navigation, and I venture to express opinion that side lights should be fixed in accordance with the Order in Council of August 1884, that they should be so fixed as to allow the direct rays of the light to be seen from right ahead on a line with the keel to two points abaft the beam.

I may mention that all the captains of this Company, and others with whom I have discussed the subject, are unanimously of the same opinions as those which I have given above.

---

16, Bernard Street, Leith,
30th August 1895.

Sir,

In reply to your circular of 25th inst., we have carefully considered the subject, and are of opinion that the angle to which ship's side lights should be screened can only be decided by a balance of advantages.

A small angle means great delicacy, and an approaching ship will indicate at once any deviation in her course; but, on the other hand, a very slight yaw will also result in the obscuration of one of the lights and will suggest an alteration in the helm which has not actually taken place. Again, with a very obtuse angle, a change in the course would not be indicated until a considerable arc had been swept out, and a vessel will seem to be keeping her course some time after she has really altered it. This disadvantage is of special consequence in narrow waters. Taking all the facts into consideration, we think that a small angle offers the greater advantage, and that the present angle of 4° is too large.

We are of opinion, however, that the angle should not be arbitrarily fixed, but should depend on the beam of the vessel, a large vessel having a greater angle; the object to be arrived at being that the rays from the side lights should cross at the same distance ahead of the stem of every ship, and we think that this distance should be fixed at not less than 300 feet for the most divergent ray.

We are, &c.
JAMES CURRIE & Co.

Chamber of Commerce, Belfast, 6th September 1895. App. 19.

SIR,

YOUR letter of 25th June has been considered by the Shipping Trade Section and Council of this Chamber; and I am instructed to say in reply that they consider that side lights should not be screened more than 2° from the outside edge of the wick, instead of 4° as at present.

I am, &c.
SAMUEL VANCE,
Secretary.

## APPENDIX No. 20.

*Papers handed in by the Chairman.*

App. 20, Nos. 1 and 2.

### No. 1.—REPORT on SIDE LIGHTS of SHIPS at SOUTHAMPTON.

All the lamps seen here were very good indeed, probably because the traffic of the port is confined almost altogether to passenger steamers of a high class.

All were of copper, with duplex and triplex wicks, and in most cases the colour was obtained by means of a coloured shade, separate from the lens, with more or less air space between; and it is worth notice that in almost every case of a lamp having the lens coloured (instead of a clear lens and shade) that lens was more or less broken.

It seems as if the shade acts as a protection to the lens from the direct and extreme heat of these powerful burners, thereby preventing the uneven expansion that would occur in such a thick mass, one side of which was exposed to the air, and lessening the difference of temperature between the two surfaces, so that when struck by a sea or body of cold spray and suddenly cooled on the outside there is not the same tendency to rupture as in the lens carrying its own colour and subject to the uninterrupted heat of the flame on the inside.

The majority of the wicks were 1 inch in width, and placed at an angle of 45° to the fore and aft line. In many of the duplex lamps the flames blended and passed through a single opening in the cover.

Triplex wicks gave a very broad flame and of a varying breadth, as it was measured along the side of the triangle or along the line joining apex and base. Each wick had a separate shaft and wheel, so that in whatever position it was placed, it was difficult, if not impossible, to turn one wick without unshipping the whole lamp.

The electric lights found were of 32 c.p., double filaments without curl, placed parallel to one another and at such a distance apart that in whatever position they stood the difference of width of the illumination was practically nil.

Although some of the lamps had not been cleaned since use, no vestige of the accumulation of dirty oil in the angle of the glass was observed.

Notwithstanding the high class of lamp in use, and the expensive mountings, &c., cases of carelessness were found which entirely put all regulations on one side. One or two may serve as examples.

*A.* A 20-knot steamer trading across Channel in all weathers and at all hours had her side lights on the bridge, but so fitted that they must be taken out to trim as there was no means of getting at the door. Her spare lights were *in store on shore*, so that not infrequently she must have been without a side light showing.

*B.* A coaster, trading all round England and Ireland, mostly at sea at night.

Her screens were on the forecastle on davits which turned in when going in or out of docks (an almost daily occurrence) kept in place to the right angle by a hooked stay. This stay, on port side, had been accidentally bent and never straightened again, so her angles of screening were not alike.

In practice, however, these screens were not always used. For bad or dirty weather, movable screens had been made which hung by hooks on the end of the bridge rails. The lights were carried in them.

The angles had not been tested!

*C.* A well found ocean liner, carrying mails, whose triplex lamps swing in gimbals in lighthouses.

These gimbals were fore and aft, so that either the wick must be obscured by the foremost one if truly centred, or if not the slightest heel or roll would alter the position of the wick and the angle of screening + or − in accordance.

Her spare lamps were duplex, of quite a different pattern and size and not fitted for gimbals, so that if required for use a platform would have to be built in the lighthouse for them to stand on, and the angle of screening somewhat uncertain.

There was a very strong feeling that regulations should insist on some uniform method of placing the side lights with reference to the position of the masthead or steam light.

H. H. HALLETT.

### No. 2.—REPORT on SIDE LIGHTS of SHIPS at LONDON.

One of the sub-committees, consisting of Mr. Thomas Scrutton and Sir Edward Harland, visited the West India Docks on June 21, 1895, accompanied by the following Board of Trade surveyors: Captain Wilson, Captain Rowe, Captain Young. They examined the side lights of the S.S. "Atlantis," which they found fixed in lighthouses on the after end of the forecastle deck, which, together with the screens, are constructed of iron, and permanently secured to the deck, with an entrance thereto from under the forecastle.

The Committee, as carefully as possible, endeavoured to check the screening, measuring the angle of such from a centre line stretched fore and aft on the forecastle deck, with the following result, and taking the centre of the wick, as represented by the lights burning.

The port light was screened to an angle of 4·3°, whilst the starboard light was screened to an angle of 1·9°, thus showing a considerable difference, but as it was explained to the Committee that the surveyor had endeavoured to adjust these some time recently by various counter measurements taken below the deck and across, some such errors appeared quite possible. Indeed, so difficult did the Committee find it to determine or check the angle of the screens attached to such lighthouse receptacles for side lights, that they would strongly urge the necessity of a circular hole being cut in such not less than, say, 1½″ in diameter, and in a straight line between the wick of each lamp, so as to enable the surveyor to measure correctly across from the wick of the lamp to the centre line of the vessel, thus to enable him similarly to measure and thereby to adjust accurately the check at fore end of screen. The hole referred to, to be closeable watertight by a pair of iron washers and screw, as only required for removal for such adjustments.

They also inspected the side lights and masthead light of the "Amber," SS., engaged in the cable-laying service, where they also found that the side lights were enclosed in lighthouses at each end of the captain's bridge, nearly amidships. They were so elevated that the difficulty in checking the screening was still greater than in the first instance, either by lighting the lamps, as in the first instance, for observing which there was no platform or deck forward of them nearer than the forecastle, or by attempts at measurement by plummet lines or other means, by reason of

App. 20, Nos. 2–4.

the great internal height of these enclosed iron lighthouses. Hence a still greater necessity of similar holes being cut on each side for purposes of such measurements as already described. The cutting or punching of such holes by the builder in the first instance would be very trifling, and even cutting by hand would entail but little expense, perhaps 2*s.* 6*d.* per pair of side lights.

The Committee found the masthead light secured on the foretop, clear of the foreyard, and no doubt clear of the foot of the topsail when set; and it was contemplated to light the side lights also by electricity.

The four-masted sailing ship "Lough Broom" was also visited, when the side lights were also found in lighthouses on the after end of the forecastle deck. The lanterns were placed therein identically the same as in the "Atlantis," but with the screens cranked close to the lighthouses, so as to avoid the necessity of chocks. The great difficulty in this case of checking the accuracy of such being also the same as in that of the "Atlantis," for want of such holes for measurement referred to. A further attempt was not made to check the angle of these screens.

On Friday, July 5th, 1895, the same sub-committee, accompanied by the following Board of Trade surveyors: Captain Wilson, Captain Young, Mr. Lewis, followed up its investigation by boarding various classes of craft in the Thames below London Bridge, with a launch kindly lent by the Thames Conservancy Board, commencing with the ketch "Water Lily," a Newcastle trader, with side light screens carried on davits just abreast the main rigging, cranked outwards and secured from turning by square part on the davit and in rail. The starboard screen we found $1\frac{3}{4}''$ wider at the fore end than at the after end, measured from the centre line, with a chock $2\frac{3}{4}''$ thick, and the distance of the outer edge of the wick from the screen $5\frac{1}{4}''$, which practically results in the inner edge of the wick and the outer edge of the chock being parallel with the line of keel. The screening of port light was not tested.

We then visited the "Victoria" paddle steamer, a Southend boat, where we found the screen on the port side $1\frac{3}{8}''$ more outboard at the forward end than at the after end, measured from the centre line; thus resulting in the line from outer edge of wick to chock giving 3° of screening, or the chock being thus $\frac{3}{8}''$ too thick to give 4° of screening, with a distance of $4\frac{1}{4}''$ from the screen to the outer edge of wick, and with a chock $1\frac{3}{8}''$ thick.

The three-masted schooner, "Queen of Mistly," we then inspected, with side lights carried on davits outside main rigging. The port screen measured 3′ 2″ from wick to chock. We found the forward end of screen 2″ outside the line parallel with the keel, with a distance of 6″ from screen to the outer edge of wick, and with a chock $3\frac{1}{8}''$ thick, practically resulting in a line, if taken from inner edge of wick to outer edge of chock, being parallel with the keel, or to screen being 2° from outer edge of wick to chock, or in the chock being $1\frac{1}{2}''$ too thick to give a screening of 4° as at present required.

We also saw that the "Perth" SS. of Dundee, had electric side lights, in a lantern and screen immediately above oil lights with lantern and screen, at either end of the captain's bridge amidships.

We are thus led to conclude that there is great irregularity in the screening of side lights in the smaller classes of sailing craft especially, as well as the smaller steamers, though it is possible that such may be accounted for by the very portable manner in which some of them are either allowed to carry their side lights, or that the exigencies of the trade in the working of cargo over almost every point in the bulwarks may present difficulties not yet overcome in side lights being carried in more permanently fixed positions, with a fair chance of such remaining accurate in the intervals between the surveys.

Thomas Scrutton.
E. J. Harland.

1st August 1895.

---

No. 3.—Report on Side Lights of Ships at Cardiff.

On July the 6th and 8th we visited the docks at Cardiff for the purpose of inspecting the fittings of side lights and screens.

On the 6th we inspected the vessels in the Bute Docks, and on the 8th those in the Barry Docks, accompanied by Captain Chalmers, the principal Board of Trade officer of the district, who with his assistants made the necessary observations in our presence.

We found that on an average the screens were set at an angle of 4° due possibly to the recent action of the Board of Trade in the matter. One vessel, however, we found screened to 2° 20′ and another to 5°.

The light boxes and screens were fixed in various positions, but the large majority were placed on the captain's bridge. Some were hung on to the bridge rails; many were hung on swinging davits, and a few were in towers.

As regards those hung on the bridge rail, we are of opinion that the rail is generally much too slight to ensure the screen being retained at the proper angle, any slight accident, even the pressure of a funnel guy bearing against the rail, is sufficient to alter the angle of the screen materially.

It would be better if the screens were fitted to a strong projection from the bridge (deck) itself, instead of to the rail.

As to the screens fitted on swinging davits, we found that in most cases the davits were much too slight, and often had considerable play in the sockets; and having but one stay to keep them in position when swung out, any slight accident would put them out of adjustment. It would appear desirable that the davits should be made of iron of not less than a certain strength, that they should be stepped on the upper deck, below the bridge when possible, being passed through a strong iron plate, either on or secured firmly to the bridge, to ensure their being kept in an upright position and free from unnecessary play, and two stays should be used instead of one to prevent any movement of the screen.

In one very well found steamer we found electric side lights fitted in towers under and supporting the bridge, apparently a very good arrangement if sufficiently high to clear the obstructions on the forecastle. In this vessel, however, they had been condemned by the Board of Trade as the lights were interfered with by ventilators on the forecastle, and screens for oil lamps had been fitted at the ends of the bridge. But as the electric fittings were all intact and the lamps in place ready for use, we are of opinion that in all probability they had been in use, notwithstanding their having been condemned, which points to the necessity of having faulty fittings in this respect either rectified or *removed* under the authority of the Board of Trade.

In many vessels we found the coloured lenses cracked, and this was much more frequently the case with the green than with the red lenses. We consider that the plan (approved we believe by the Board of Trade) of using uncoloured lenses and coloured shades between them and the light far preferable to colouring the lens itself, as the shade appears to protect the lens from the heat of the lamp, and so prevents its being cracked; the thin glass shade expanding or contracting more freely does not so easily crack, nor is it exposed when very hot to the cold spray as is the lens. Moreover, if cracked, it is readily and inexpensively replaced.

H. G. Andoe, Rear Admiral.
John S. Castle.

24th July 1895.

No. 4.—Report on Side Lights of Ships in the Tyne District.

The lights I investigated were those of steamers, taken quite by chance, without previous selection, and fairly representative of their class.

Five ships were inspected, and in four of these there was a striking want of cleanliness in all that concerned the lighting apparatus and glasses, which I attribute either to a lack of sufficient hands on board, or to ignorance of the great importance of freedom from dirt and oil in ensuring that the lamps give their full complement of light through clear glasses, as well as that they show over the full arc of 10 points.

Many lamps fitted so loosely in their seats as to be easily subject to misplacement, and consequently to alteration in the direction of their light.

Some lamp frames were fitted with two slides, one for use with vegetable oil, the other for use with mineral oil. Should an error occur in the use of the slides the light would be somewhat affected.

In the case of one steamer which had lights fitted in lighthouses, the lower part of which formed w.c.'s, the

lamps could only be got at with difficulty, and I think the three ½" strips down the protecting glass of the towers tends to diminish the light.

The burners were generally placed at an angle of 45° with the fore-and-aft line of the ship, but owing to the burners being fitted with screws, this angle might sometimes not be reached or it might be exceeded. These facts emphasize the desirability of there being some uniformity in the pattern of lamps. They need not necessarily be of an expensive material, but all should follow one pattern, the cost varying according to the materials used. There is no reason against, nor any mechanical difficulty in carrying out such an idea.

*Steamers examined, with Angles of their Side Lights.*

| Steamer. | Angle of Starboard Light. | Angle of Port Light. |
|---|---|---|
| "Bakuin" - - - | 4½° | 4½° |
| "Terra" - - - | 4⅓ | 2½ |
| "Flamboro" - - - | 1 | 0 |
| "Stag" - - - | 1⅛ | 4⅜ |
| "Prudhoe Castle" - - | 2¼ | 2¾ |

D. WILSON BARKER.

Two photographs of kind of lamp used in Tyne district are enclosed.

*Note on the Position of Lights in Steamers.*

The following are particulars as to the position of the side lights with regard to the masthead light in 162 steamers of all sorts (excepting tugs or such like small vessels):—

5 had their side lights directly under, or in the same vertical plane as the masthead light.
13 had their side lights before the masthead light.
144 had their side lights abaft the masthead light.

D. WILSON BARKER.

No. 5.—REPORT on SIDE LIGHTS of VESSELS in the CLYDE.

In August and September I visited Glasgow and Greenock with the object of reporting on the practice of fitting side lights in British and foreign vessels in the Clyde.

I visited as many vessels as possible, and also several lamp makers' places, and I inquired as to the surveyors' practice, both in Glasgow and Greenock, with the view of determining the accuracy of their method of getting the angles in screening the side lights.

*Firstly*, as regards the surveyors' mode of operation, I found that both in Glasgow and Greenock the surveyors tested their first determination of the 4° angle by enlarged similar triangles, a most excellent plan for securing accuracy of screening.

*Secondly*, as regards lamp making in Glasgow, I may say that I was desirous of testing Mr. Harvie's statements in answer to my questions (*Q.* 3666): Do the Clyde surveyors compel you to put the wicks at right angles to the fore and aft lines of the vessel?—*A.* Yes. *Q.* 3667. Because the instruction issued to them is that the wick-holder should be placed in the position of greatest efficiency?—*A.* Well, that may be so, but the difficulty about the thing is that the surveyor will pull out his book and show you private instructions, and the book does not hold with that.

Now, I am bound to say that after what appears to me to be sufficient investigation, this statement of Mr. Harvie's as to the practice of the Clyde surveyors is not borne out. No other lamp maker whom I visited had ever heard of such coercion on the part of the surveyors, and none of these makers puts his wicks at right angles to the ship's fore-and-aft line. Straight wicks are usually placed parallel to the chord of the lens, and, in the case of one type of excellent lamp much used in the Clyde, having a lamp with a curved wick, the horizontal curve of the wick is concentric with the horizontal curve of the lens. I believe one of the diagrams of wicks in the public (not private) instructions issued to the Board of Trade surveyors has a straight wick drawn at right angles to the ship's fore-and-aft line, and I am reluctantly compelled to think that Mr. Harvie must have had something of that sort in his mind when he made his statement—a statement which appears to me to reflect unjustly upon the surveyors of the Clyde, who are men of great ability and tact.

Before leaving lamp construction in Clyde workshops, I may point out that unless the cost of side lights is to be much increased, makers must still be allowed to cut three lenses out of one cast circle of glass. Now the Board of Trade have recently recommended or enforced the increase of the length of arc of the lens, so as to overlap at both ends the ten-point arc, the object being to allow a margin at both extremities of the lamp for dirt in badly-cleaned lamps, and to prevent this dirt encroaching on the necessary ten points of illumination. Mr. Samson specially spoke to this. It appears that the makers of less expensive types of lamps still cut three arcs out of one circle; but this, with the extra dirt-trap arc, makes the third of the circumference of the circle of glass come rather within the ten-point clear arc; and two methods are adopted by makers to approximately remedy this; one is to turn the whole lamp round horizontally, so as to allow plenty of the clear glass fore and aft, which results in scrimping the light two points abaft the beam; the other is to put the wick closer to the lens than its proper position in the centre of horizontal curvature of the lens. Both plans are bad. In the first case the full light is apt to fail to show two points abaft the beam (one case which I measured gave the centre of the wick about two points abaft the beam); but this, perhaps, is a matter of not much consequence. In the second case the practice of putting the wick nearer the lens is radically bad, because it not only prevents the light from passing through the lens without refraction (actually in this way lessening the necessary ten points of uniform unbroken light), but it tends to increase the chance of breaking the lens by bringing the light (and therefore heat) nearer to the lens.

The greater part of the Clyde made lamps appear to have a thin film of colouring matter put on the coloured lenses. The very bad practice of colouring the lens right through does not seem to be adopted; and the practice of using white lenses with a flat coloured shade interposed between the source of light and the lens does not seem to be common, although this last is a good plan (provided the flat shade has no optical defects) as it diminishes considerably the chances of cracked lenses; and indeed white glass shades are fitted for that purpose in some optical lanterns used in scientific investigation. I may say, however, that notwithstanding the practice in the Clyde, I saw only one cracked lens, and the crack in that case did not interfere with the optics of the lantern.

*Thirdly*, as regards the screening &c. of the lamps which I examined in ships, it appears that little or nothing is to be desired as regards British vessels. If anything is faulty it is the poor character of the type of light used in some of the smaller coasting sailing vessels.

But the same thing can hardly be said of the vessels under foreign flags. In these the faults are two: 1st, the fixing of the lamps; 2nd, the character of the spare lamps for replacing the original lamps.

In regard to the second of these points, I may briefly say that in every case inspected the replacing lamps were smaller than the original lamps, and their light would cross the bow at a smaller angle than the original lamps.

But the point calling for special condemnation is the flimsy style of fixing the lamps. For instance, I saw a case where a cargo steamer of considerable size had her lights of the type of arrangement so common (viz., drawn inboard without detaching the screen when in harbour, and pushed out when at sea); and with the whole arrangement fixed in position when in use by a weak hooked stay, capable of being easily bent by the blow of a sea, and when bent throwing the screens, lamps, and angles of screening out of adjustment.

Other instances (extremely abundant) are to be seen in sailing ships which have their screens and lamps attached to a kind of removable davit, so as to be taken out of position entirely when in dock (and possibly also at sea). This removable arrangement sometimes has the screen box detachable and detached from it, and sometimes the box remains permanently attached to it. In numerous cases of vessels in dock, these stanchions, with or without the screen box attached, were lying

App. 20, No. 5.

promiscuously about the deck. Where the screens were detached, the stanchions formed handy levers for purposes about deck. No wonder need therefore be expressed that the stanchions were, in almost every case inspected, bent. The consequence would be that the screens and lamps would be thrown out of proper adjustment.

In one sailing vessel (a foreigner) examined more in detail, I found that the starboard lamp in use was a fish globe lantern (it was explained that the one first furnished had been broken), and the port lantern in use was a dioptric one. On testing the screening it was found that the outer edges of the wick were apparently crossing the outer edge of the screen at an angle of 4°; but a scrutiny of the screens showed that both were 2o out of the fore-and-aft line, thus reducing the 4° of crossing to 2°. When the spare lamps were produced I found that these were smaller than the lamps in ordinary use.

The foreign vessels whose lamp arrangements were defective belonged to the north and to the south of Europe; none of them were French and German.

The conclusion appears to be that considerable improvement in the side lights of these vessels is desirable, and failing that, it is evident that nobody will ever be certain what the lights of these vessels will be screened to.

J. Bolam.

## APPENDIX No. 21.

*Abridged and Amended Paper handed in by Vice-Admiral P. H. Colomb.*

App. 21.

SUMMARY HISTORY of the RULE OF THE ROAD AT SEA, showing its bearing on SCREENING.

The earliest note of a rule of the road is by Sir Rich. Hawkins, 1593.

In the time of Charles II. in the Navy, junior officers "gave way" to seniors.

Before 1780 this was altered; when it was necessary for them to cross near each other, ships on starboard tack held their wind, and ships on port tack "bore up" and "passed to leeward."

In 1780 all ships on port tack "bore up" for ships on starboard tack.

In 1799 "the ship on the starboard tack was always "to keep the wind, and that on the larboard tack was "always to pass to leeward, except in cases where "extreme danger might arise from a strict compliance "with this instruction." Ships at night carried one light at each cathead, and were to show a second light at the weather cathead if they intended to bear up, and at the lee cathead if they intended to hold their wind. (Really one light at starboard and two lights at port cathead.)

In 1831 a Committee of House of Commons recommended that when two steam vessels found themselves "unexpectedly near each other 'stem on,' they were "to put their helms a-starboard." This was in view of river navigation.

In 1836 a Royal Commission declared that the rule for sailing vessels "that when two vessels meet on "contrary tacks, the one on the larboard tack should "bear up, and that upon the starboard tack should keep "her wind, had been attended with the best effects."

They proposed that steamers in rivers should "keep "on that side of the river or channel which lies on "their starboard hand." It was proposed to display lights on a yard across steamers' masts, with lights to denote going up or going down the river.

In 1832 the rule in the French navy "expressly ordered" the ship on the port tack to bear up, and the ship on the starboard tack to hold her wind.

*Note.*—That until 1839 nothing was said of "close-hauled" and "free" ships. Nothing of steam or other ships porting their helms except the proposal of the Commons Committee in 1831.

*Note again.*—That the only rule known in the open sea was that the one ship should keep her course, and that the other should *turn towards her and pass under her stern.*

In 1839, the rule in the Navy was: "When ships on "different tacks must pass near each other, the ship ON "THE STARBOARD TACK IS ALWAYS TO TO KEEP THE WIND, "and that on the larboard tack to pass to the leeward, "bearing up in time for that purpose.

"When STEAM VESSELS not under sail, but on different "courses, must unavoidably or necessarily cross so "near that by continuing their respective courses there "would be a risk of coming in collision (*Note* that "this was the first time any such expression was used) "they are always to pass ON THE LARBOARD SIDE OF "EACH OTHER.

"A STEAM VESSEL passing another in a narrow "channel must always leave the vessel she is passing "ON THE LARBOARD HAND."

These two last were nearly the rules published by the Trinity House in 1840 for general use. The preamble ran: "Whereas the recognised rule for sail-"ing vessels is that those having the wind fair shall "give way to those on a wind."

(*Note.*—There was no such rule at the time known either in the English or French Navies.)

"That when both are going by the wind, the vessel on the starboard tack shall keep her wind, and the one on the larboard tack bear up, thereby passing each other on the larboard hand.

"That when both vessels have the wind large or abeam and meet they shall pass each other in the same way on the larboard hand (*Note* that there was no such rule at the time in the English or French Navies); to effect which two last-mentioned objects the helm must be put to port. (*Note* that the helm of only one ship was put to port in the first case.)

"And as steam vessels may be considered in the light of vessels navigating with a fair wind, and should give way to sailing vessels on a wind on either tack, it becomes only necessary to provide a rule for their observance when meeting other steamers or sailing vessels going large."

The rules above were then promulgated, having no doubt been agreed upon with the Admiralty the year before.

*Note.*—That besides professing to base the new rule on other rules which were unknown to the English and French Navies, the analogy was wrong, for in any case crossing, with the courses at greater or less angles was the position to be provided for; and a rule analogous to this for sailing ships would have directed the steamer with the other on her port side to keep her course, and the steamer with the other on her starboard side to have put her helm to port to pass under the stern of the other.

At this time steamers carried one white light at the masthead, and were given no means of distinguishing their port from their starboard side, which sailing vessels had possessed for so many years.

In 1844–5 Messrs. Chapman and Company circulated a paper, afterwards well known as "Chapman's Rules" which were held to embody the existing law. It gave the rules in short, as above, and proposed a new (and properly necessary) rule that free sailing ships should carry a single light at each bow to distinguish them from steamers with the single light at the mast head, and sailing vessels by the wind, with one light on the starboard bow and two lights on the port bow.

In 1846 an Act for the "Regulation of Steam Navigation" ruled that steamers were to pass port side to port side, and to the starboard side of narrow channels.

About 1848 red and green side lights had been partially introduced in the Navy.

In 1851 an amending Act made—apparently by mistake—this rule applicable to all British ships, sailing as well as steam, but made no corresponding change in the lights.

*Note.*—In this Act the full expression "risk of collision" was used for the first time. The courts have sometimes ruled that the law is to prevent "risk of collision," and should be put in force before it arises.

In 1852 the red and green side lights were ordered to be carried by all British steamers, but no change to correspond was made in the rule of the road.

In 1854 the Act ruled thus:—

"Whenever any ship, whether a steam or a sailing ship, proceeding in one direction, meets another ship, whether a steam or a sailing ship, proceeding in another direction, so that if both ships were to continue their respective courses they would pass so near as to involve any risk of a collision, the helms of both ships shall be put to port, so as to pass on the port side of each other."

*Note.*—That the law was to be put in force not *after* risk of collision had arisen, but in order to prevent any such risk arising which would have arisen if the law did not step in.

*Note.*—That Admiral Beechey, who was the promoter of this law, published a justification of it next year. He drew diagrams to show that ships in turning moved over the arc of a circle of considerable magnitude. But he did not produce a single diagram applying the data to his rule in any ordinary case of ships approaching each other whose paths crossed at large or small angles. He only gave the exceptional case where paths crossed at right angles and each ship travelled in turning towards one another over an identical path. If he had applied his data he would have seen (1) that his rule would take ships into collision when if they had let things alone they would have gone clear; and (2) that where there was a real risk of collision both ships porting their helms would make it certain, while if both ships turned towards one another—one ship starboarding and the other porting, collision would have become impossible.

In 1860 a Parliamentary Committee condemned this rule as "most unsatisfactory, however the decisions of "our Courts of Admiralty may have modified its "dangerous tendency."

*Note.*—What the Court of Admiralty did was to hold generally that for sailing ships whose courses crossed at a greater angle than about two points, the old rule for crossing ships, and not the new one, held good. For steamers they could not limit the new rule, for there was no other.

New rules were devised of considerable complexity. Though it could have been shown that even within the two-point crossing angle collision under port helm was certain, when if one of the ships starboarded *towards* the other it became impossible, yet the new rules made no crossing rule for steamers, and altered the old rule for sailing vessels by changing the phrase "give way," which clearly meant "pass under the stern," to "keep out of the way," which left it designedly open to the old "giving-way ship" not to give way, but to leave an unregulated struggle between the ships as to which could cross in front of the other. But while the old "giving-way" ship was thus authorised not to "give way" she was forbidden, if a steamer, to use the speed which might be necessary to make the manœuvre a safe one. In the same way the steamer and the sailing ship were authorised to contend for the right of crossing—a right which it had been the whole aim of the old rules to keep sacred for one ship of the pair.

But the new rules prominently retained the rule, both for sailing ships and steamers, that directed port helm for both on approaching, and which had been so strongly condemned by the Parliamentary Committee. It was hoped to restrict its evil influence by limiting it to the undefined and undefinable position of "end-on or nearly end-on."

Before the new rules passed into law, a crossing rule for steamers was introduced on the recommendation of the French Government, which would have been strictly analogous to the old rule for sailing ships crossing on opposite tacks, had the phrase used been "give way" instead of "keep out of the way," which was that introduced.

The limit to the port helm rule stated in the new Rules had little or no influence on the decisions of the Admiralty Court, or even over the courts set up by the Board of Trade, or on the Wreck Commissioner's Court. The Admiralty Court still held generally that port helm for both ships was proper when the courses crossed at any angle up to two points; and further generally held that it was not lawful for two ships to pass one another starboard side to starboard side, unless the distance likely to be between them in passing was considerable.

As the very large number of collisions had always occurred under the conditions within which the port-helm rule was held to act, it followed that the great majority of the decisions, especially in night cases, were delivered under the port-helm rule, and the ship which had not ported was generally condemned. The natural result was that the condemned law of 1854 continued in full operation. It became a matter of little consequence to the seamen what coloured light or lights were seen, or where they were seen. It was a legally safe thing to port the helm, no matter what came of it, and the claim to have ported the helm was generally made.

Before 1863 (in 1858) sailing ships had been directed to carry coloured side lights according to the rule for steamers; but the usual screening adopted allowed the rays to cross 9°, or even more, to the wrong bow. Practically it may be said that both lights were generally visible from a position of a point on one bow of any ship to a point on the other bow. In many collision cases both lights were seen from either ship at some time before the collision. But as on the one hand, the rules were held to oblige a steamer to port her helm to a green light shown by another steamer, when it was at all fine on the starboard bow; generally to port the helm if such green light was seen on the port bow; and in any case which was clearly not "end-on or nearly end-on" allowed her to starboard the helm to a steamer's red light seen on the starboard bow; or in any case of approaching a sailing vessel, to port the helm to her green light, or to starboard it to her red one; the colours of the lights had lost all significance for steamers. They acted independently of colour; and whether one light or both lights were seen was not of consequence.

It was the same for sailing vessels amongst themselves. The port helm rule for "nearly end-on"—or as they were then called in the courts, "meeting" cases—necessarily ignored the colour of the light seen. In "crossing" cases, the new rule had expressly authorised the ship on the port tack to ignore the red light seen and to starboard her helm to it.

No question could have arisen as to the screening of the lights under such conditions of the law. It did not matter how much the lights showed on the wrong bow, because if the lights seen might possibly denote a "meeting" case, the helm must be ported without reference to the colour of the light seen; if the lights seen seemed to denote a "crossing" case it was always a matter of "judgment" which way to put the helm.

Moreover, the state of the law as it bore on the screening of the lights was this: a ship might have ported her helm to a red light seen very nearly ahead, and while she was turning, might see the green light added to the red, and then see the red light disappear, and yet not be justified, under the law, in reversing her helm.

Up to 1867, none of all this mischief was seen. The practice of porting the helm was almost universally held to be a good one, and the rule a good rule. Collisions were held to be caused, not by the ship which had first of all ported her helm, but by the ship which had either delayed or neglected to port. It seemed to be nowhere understood (1) that the cases where a collision otherwise probable, but avoidable, could only be avoided by both ships porting their helms, were, and must be from the nature of ship's movements, infinitely rare; and (2) that the cases where probable collision, otherwise avoidable by proper helm, would be made certain by both ships porting their helms, must be, and were, very common.

It seemed nowhere to be understood that coloured side lights, properly screened so as to show as little as possible on the wrong bow, were of themselves—provided the signals made by them were obeyed—a very perfect preventive of collision without any rules at all. It was nowhere understood that, according to the nature of ships, a properly screened *green light* seen in any direction was a clear signal *not to port the helm*, and in certain directions was a signal to *starboard* the helm; that a properly screened *red light*, seen in any direction, was a clear signal *not to starboard the helm*, and in certain directions was a signal *to port the helm*. Moreover, that *a change from red to green* anywhere ahead was always a signal *to starboard the helm*: while *a change from green to red* was always a signal *to port the helm*.

The disaster to the "Amazon" and "Osprey" in 1867 only partly revealed the mischief underlying the law and the screening of the lights. The defect of screening was here that the "Osprey" saw, nearly ahead, only the "Amazon's" red light when she ought only to have seen her green. The defect of the law

App. 21.

was shown, inasmuch as it justified the "Osprey" in continuing port helm after she had seen green added to red by the crossing of the "Amazon's" lights to the wrong bow, and then green only visible by the starboarding of the "Amazon's" helm. The justification for the law was that the movement of the "Amazon" was illegal. But it was not shown to be necessary that the illegal movement of one ship should consign both to destruction. Nor was it shown to be necessary that the law should enjoin disobedience to the plain signals made by the lights.

If the "Osprey" was directed by the law to port her helm, she was directed by the lights she saw to starboard her helm; and it was not shown to be necessary that she should be placed in such a dilemma.

So, as the points were not clearly seen, the steps taken were not such as to prevent the recurrence of similar accidents. No immediate steps were taken to place chocks so that the green light should cross as little as possible to the port side; and that the red light should cross as little as possible to the starboard side.

The "Explanatory Clauses," introduced in 1868, only aimed at limiting the crossing angle within which the port helm rule was to operate; they did not in the least aim at preventing repetitions of the "Amazon" and "Osprey" accident. In 1878 the "Bywell Castle" destroyed the "Princess Alice" and 600 lives under precisely similar conditions, and was justified by precisely the same reasoning that justified the "Osprey" in 1867. The "Bywell Castle" had a distinct order from the law to port her helm, but she had a distinct order from the "Princess Alice's" lights to starboard her helm. She was left in the same dilemma as the "Osprey," and judgment remained to the effect that the signals made by the lights could not be brought into harmony with the law; that the safety of shipping was better guaranteed by a law which was devised before coloured lights were devised, than by accepting the signals made by the lights as the better guide.

But on the other hand the "Explanatory Clauses," which limited the obligation to port the helm to those cases where those in the one ship saw both coloured lights in such a position as led them to suppose those in the other ship saw both of theirs, had a distinct effect, though they said nothing to relieve a ship from porting her helm when the *addition* of the green to the red light gave her a distinct signal to starboard it; yet, even with lights seen a point on the wrong bow, they made the Admiralty Court take cases under the "crossing" rule which would formerly have been taken under the "meeting" rule. And, though the "crossing" rule permitted seamen to ignore the colour of the lights seen, it was a step in advance, for seamen did retain in many cases a clear idea that a green light ahead or in the bow was a signal not to port the helm.

But the clauses, by directing attention to the screening of the lights, and by causing the introduction of chocks upon the screens which at least greatly limited the arc over which both side lights could be seen together, did greatly lessen the influence of the port-helm rule. And though it may not yet be fully comprehended that such a rule is always either unnecessary or dangerous, yet the improved screening of the lights has almost wholly destroyed its influence. Seamen so seldom see both lights together in any position that they rarely feel themselves under an obligation to port their helms, unless they have good reason to know that it is a seamenlike, and not merely a legal, act. The result is that they are better prepared to use the helm which the colour of the light seen prescribes, and no other, than they used to be.

Now, when the Washington Conference Rules for crossing ships become law, the confusion as to the meaning of colours—first introduced by retaining a port-helm rule for steamers and sailing vessels when the introduction of the coloured lights had taken away all excuse for it; and enforced by the abolition of "giving way" in the rules of 1863—will be greatly cleared away.

It will then no longer be free to the "giving-way ship" not to give way. A "giving-way ship" porting to a green light, or starboarding to a red one, according to her "judgment" at the moment, must justify a movement which, unless it can be justified, will be illegal. At present such movements rarely meet distinct condemnation in the courts; they could not, because the phrase "give way" was expressly abolished in order to permit them. But under the new law, such movements will be fastened on by Counsel as *primâ facie* illegal.

As no collisions involving coloured lights occur unless this disobedience to signals occurs also, we may certainly expect the happiest results to follow the change in the law. But then it is absolutely necessary so to screen the lights so that they show as little as possible on the wrong bow.

To the extent that they show on the wrong bow we are (1) encouraging the action of the condemned, and demonstrably evil, port-helm rule; and (2) counteracting the intent of the new law which aims at enforcing obedience to the signals made by the lights seen.

P. H. Colomb.

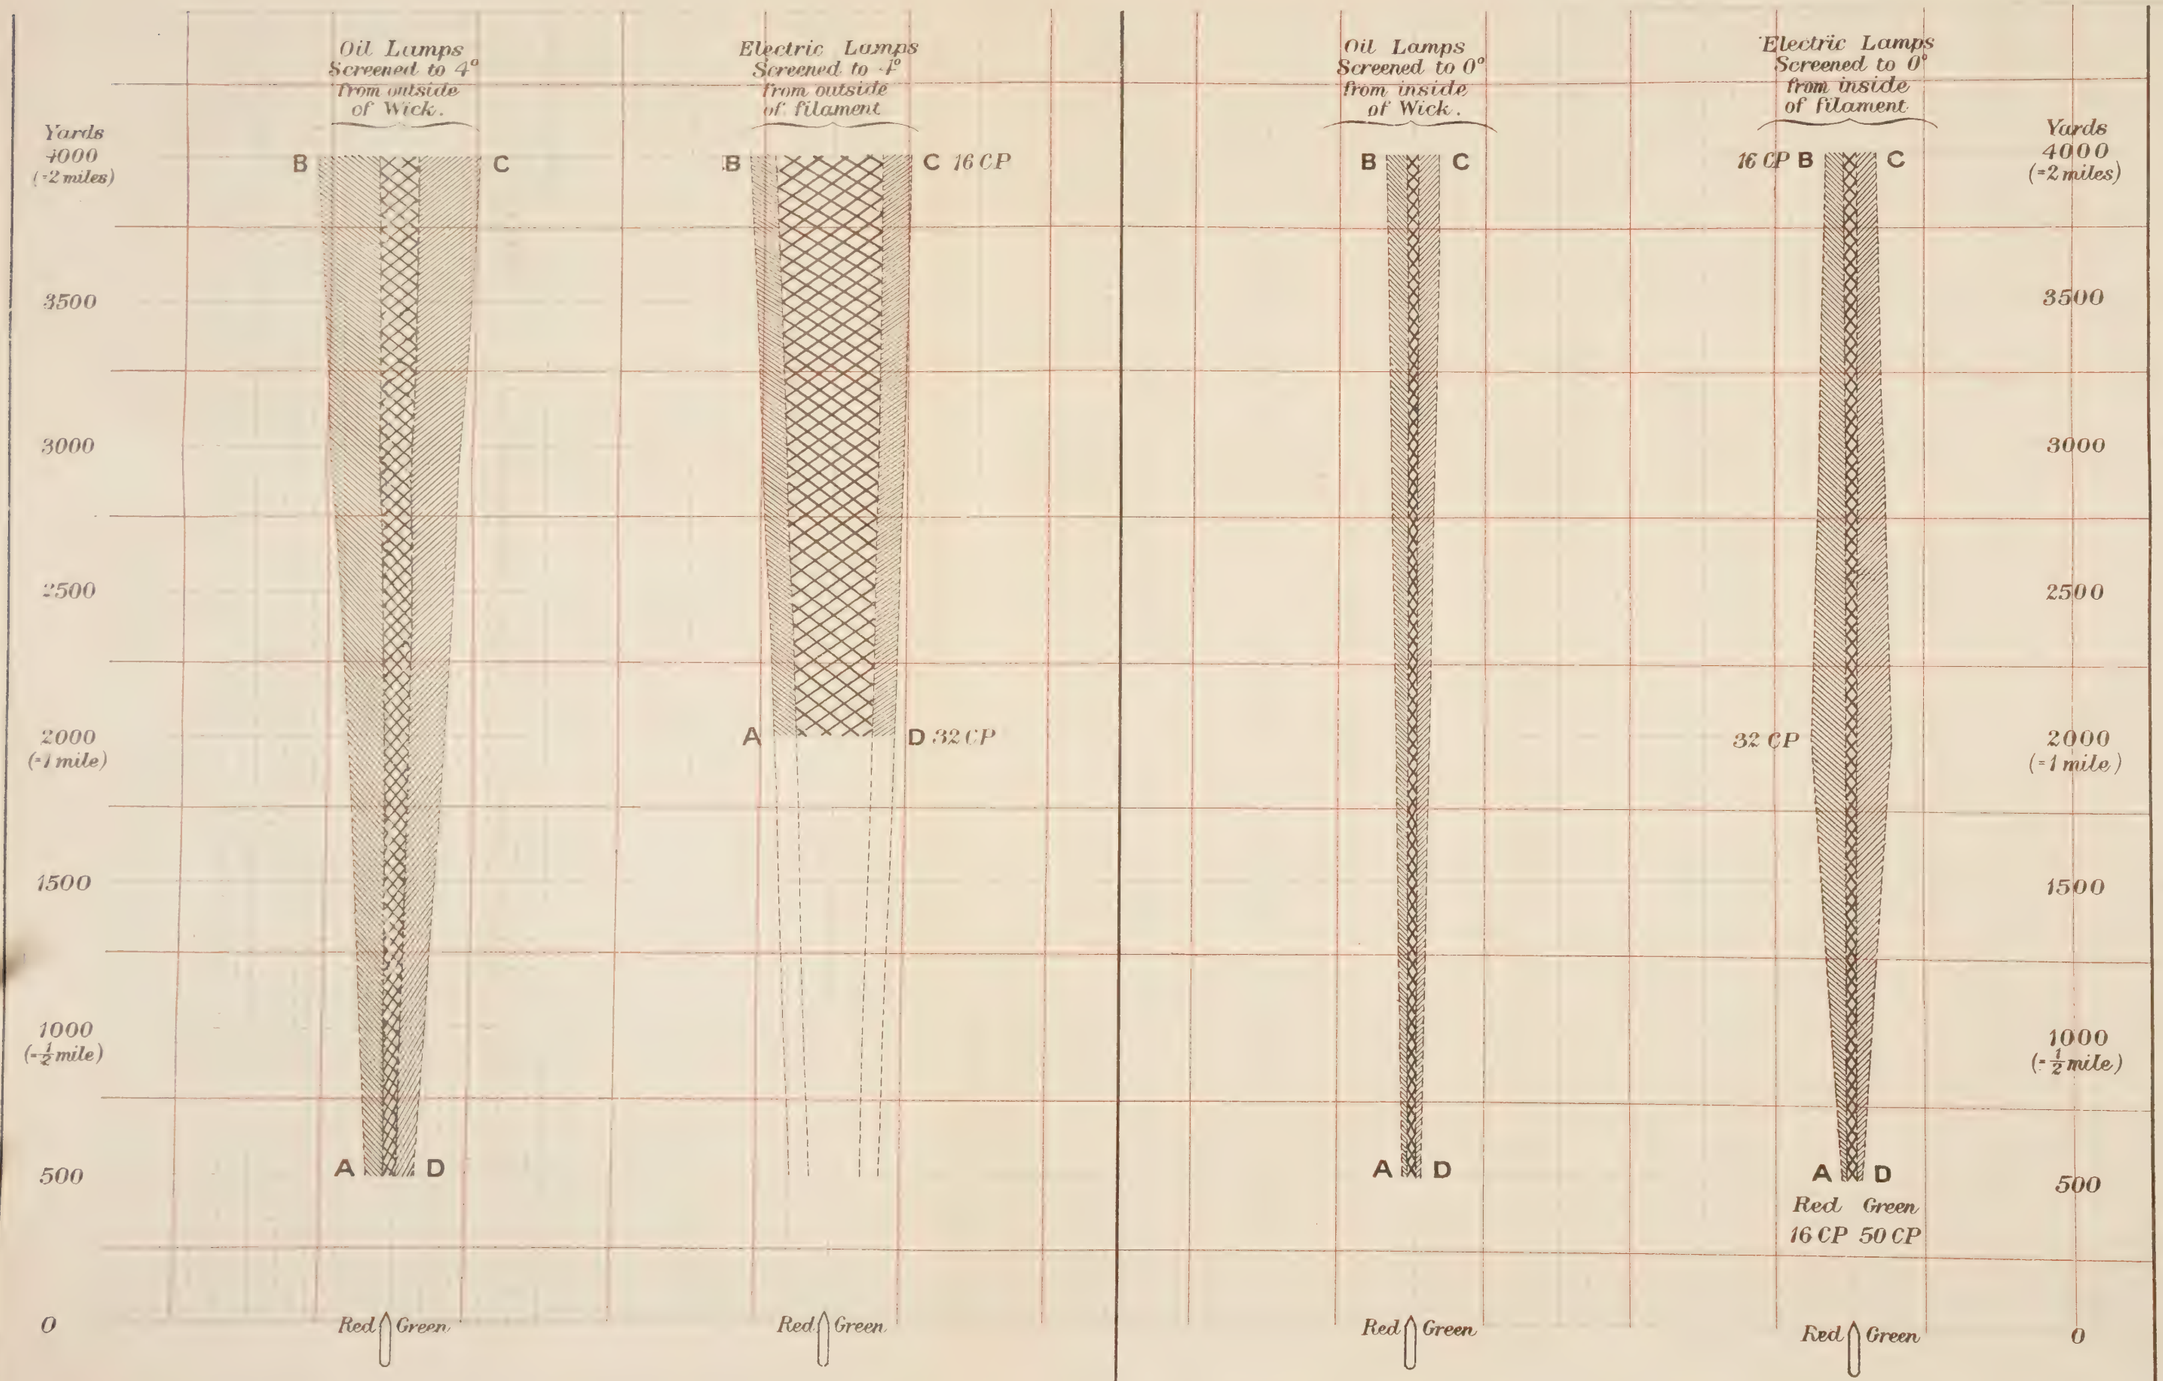
*Shoeburyness Experiments of 12th, 13th, 14th June and 25th, 26th July 1895 by the Side Lights Committee.*



## EXPLANATION.

*The Space cross hatched shews the space in which the full force of both Side lights was seen.*

*The Space shaded shews the space in which the green light was seen, but becoming less strong untill it disappeared.*

*The Space shaded shews the space in which the red light was seen, but becoming less strong until it disappeared.*

*The Areas ABCD therefore measure the spaces within which another vessel could see both Side lights of the vessel in the diagram.*

*The four diagrams accurately represent what was seen at the Shoeburyness Experiments of 12th 13th 14th June and July 25th 26th 1895 with Oil Lamps and Electric Lamps with the wicks and filaments similarly placed in the lamps and similarly screened so as to make the results of the observations comparable*

*Everything, including the vessel, is drawn to the scale of 500 yards to the inch.*

*The field between AD and the vessel exhibiting the lights is not filled in because the observations did not supply sufficient materials for that part of the field*

J Bolam.

Wyman & Sons, Lt. Lith 7515. II. 95.

# INDEX.

ABAFT THE BEAM, accurate screening not necessary, *Samson*, 437–8; *Colomb*, 2633. Accurate screening ahead much more important, *Ruthven*, 2156–66. Lights should show accurately abaft the beam, *Chandler*, 2789–91. Screens fixed in Navy abaft the beam, *Phillips*, 5159, 5180.

ANDERSON, Mr. J. G. S., one of the managers of the Orient Company, 1020-1232, and App. 6. Position of shipowners with regard to screening, 1084–94, 1097–9, App. 6, No. 3, 1198–9. The Instructions of 1875, 1103–4; the origin of the 4° rule, 1087, 1092–3, 1097–8, 1105–7, 1224; the recommendation of the Washington Conference, 1095–6, 1156, 1228; condition of screening prior to 1892, and the effect of the new rule, 1088–9, 1124, 1157–62, 1165–72, 1198–1201, 1203–16. Objects to new rule as contrary to the international regulations, 1102, 1125–7; and as causing uncertainty, especially in narrow channels, 1128–9; instance of collision probably caused by screening, 1187–97. Lights should be screened as nearly parallel as possible consistent with showing full power ahead, 1102; inner edge of wick suggested, 1103, 1109–11, 1113–8, 1134–42, 1221–4. Screening as affecting ships meeting nearly end on, 1145–55, 1173–82, 1163–4. Electric light will probably require special screening, 1108, 1226–8; candle-power employed, 1143. To secure uniform screening, it is necessary the lamps should be uniform, 1099.

BARKER, Captain Wilson, a member of the Committee. Describes his experiments with side lights, 4880–1, App. 11.

BOARD OF TRADE, Evidence on behalf of. *See under* HOWELL, MURRAY, SAMSON, RAMSAY, CHALMERS, RICHARDS, LASLETT, TAYLOR.

CHALMERS, Captain A. J. G., Principal Officer of Board of Trade, Cardiff District, 870–932. Meaning of the regulations, 878–81. Screening prior to 1892, 882–90, 896, 903–10, 912–14, 923–28. Sailors' knowledge of screening, 891–5. Screening of foreign ships, 897–9, 911, App. 5, No. 1. Reasons for approving 4° angle, 900–2, 929–32. Answer to objection to 4° screening, 915–22.

CHANDLER, Captain S. R., 2762–859. Before 1892 lights were screened anyhow, 2773; many were more than 4°, 2774, 2854; seamen did not pay much attention to screening, 2775–6. Four degrees is too much, 2769; the dark lane is not a practical danger, 2786–9, 2814–5; lights of his vessel were visible from the stem-head, 2787. Lights should be screened to the middle of the wick, 2770, 2787–1; they would not then show so much on the wrong bow, 2782–3; the lights must cross but the crossing should be as little as possible, 2784–5; the full light should be seen right ahead, 2810–3; screening should be uniform, 2849; lights should show the two points abaft the beam accurately, 2789–91. Heeling would not affect the appearance of lights, 2798–801; extent to which vessels yaw, 2793–4; period of oscillation, 2838–42, 2846–8; yawing always recognised as such, 2795–7; yawing less liable to mislead if screening is fine, 2846–8. Ships meeting nearly end on and screening, 2817–28, 2831–4, 2843–5. Electric light gives a sharper cut-off than oil, 2796; it is coming more into use, 2802–3; lamps should be uniform as to visibility, 2835–7.

CHAPMAN, Captain, Superintendent of the Royal Mail Company, 4074–200. Before 1892 thought lights were screened to inner edge of wick, 4099. Objects to 4° rule, because one vessel may see two lights while the other sees three, 4080–9, 4104–7, 4152–5; whether this might not occur with any screening, 4154; new rule makes vessels port unnecessarily across one another's bows, 4108–16. Ships meeting green to green and screening, 4090–2, 4133–42. Lights should be screened to the inner edge of the wick, 4092–8, 4117–23; this would satisfy nautical opinion, 4103. Triplex wicks described, 4118–31, 4143–9, 4156–72. Lights should be placed below masthead light on forecastle, uniform angle would be desirable but difficult to attain, 4174–4200.

CHOCK, how it acts in cutting off the flame, *Mensing*, 3213–7. *See also* SCREENS.

COLOMB, Vice-Admiral P. H., 2532–761. History of the Rule of the Road so far as regards screening, App. 21; Defective screening and defective state of the law caused many collisions prior to 1867, 2537–55; Courts held that "end on" covered a difference of two points in the courses, 2694; was the first to call attention to the bad screening, 2737–9; the screening then was much coarser than now, 2615–7; chocks began to be fixed in 1868, 2740; collisions from wrong port helm consequently reduced, 2680; the Board of Trade Instructions of 1875, 2556, 2559; seamen did not know much about screening, 2578; the 4° rule was not necessary, but it has done no harm, 2736. Lights should be screened to the inner edge of wick, 2563, 2575; reasons for preferring the inner edge, 2575–7; it would allow a certain amount of crossing, 2579–81; the lights should cross as little as possible, 2574, 2750; the objection to crossing lights is that the wrong light may be seen alone, 2573, 2637, 2709; not necessary that full light should be seen ahead of keel, 2570; meaning of right ahead, 2618–22; dark lane no danger, 2572, 2651. Ships meeting nearly end on and screening, 2582–614, 2670, 2683–92, 2696–709, 2751–61; would screen without reference to the definition of nearly end on, 2623–32; dangerous to port across a ship's bows at half a mile distance, 2664–71. Port helm was diminished with improved screening and would disappear with parallel screening, 2634–9. Screening more important at long distances, 2641–53; not necessary to screen lights abaft the beam, 2633; the lens should be larger than 10 points, 2654–63. Opposed to additional lights, 2736; standard lamps, 2747–8. Position of lights, value of indication given by masthead light, 2672–8, 2681–2; value of fixing the position uncertain, 2714–30; simplest way of showing changes of course, two white lights at an angle of 45°, 2730–5.

COLOUR, as affecting visibility, *Murray*, 4989–92, App. 2, No. 13*a*. Colour of green light as affected by electric light, *Murray*, 4881*a*–917, 5129–33, App. 13, No. 1; *Ruthven*, 2191–201; *Harvie*, 3664–5. Blue-green the best colour, *Hogg*, 1763; *Harvie*, 3621–2. A standard colour imperative, *Harvie*, 3621–2. Requirement of Board of Trade Instructions, App. 2, No. 1, par. 10. *See also under* VISIBILITY.

COLQUITT, Mr. W. H., first-class Liverpool pilot, 1355–1547. Side lights should be screened as finely as possible, and the angle should be universal; 2° from outer edge suggested, 1360–1, 1392–99, 1433–4; full light should be seen ahead, 1431–2; function of side lights to show change of course, 1391; fine screening shows change of course at once, 1522–5; reasons for suggesting screening from outside of wick, 1487–93; how light shows at short distances when screened to 2°, 1433–46. Objects to 4° rule, because change of course is not indicated, vessels passing appear to be meeting and cross each other's bows, and unnecessary change of course is dangerous in narrow channels, 1362, 1382–4, 1386–9; vessels often port across one another's bows, 1501–4; evidence as to navigation in narrow channels, 1407–27, 1447–66, 1485–6, 1498–1500, 1505–11, 1516–9; dark lane no practical danger, 1390; though its non-existence shows lights must have crossed. 1402–6; ships approaching "green to green" would not be in danger even if finely screened, 1363–76; meaning of "green to green," 1467–77; extent to which vessels yaw, 1526–9, 1535–47; extent to which they list, 1533. Before new rule, was unaware that lights crossed, 1428, 1513–5; the old practice was not uniform. 1381; the new rule has increased the crossing of the lights, 1377–8. Opinion as to the meaning of "across the bow," 1379–80; "right ahead," 1479–84.

CORRY, Mr. JOHN, shipowner, 1233–353. Want of uniformity in screening caused by improper placing of the wick, 1239–40, 1283–4. Lights should be screened to the inner edge of the lens, which would be the same as the inner edge of the

CORRY, Mr. John—*cont.*
wick in a properly constructed lamp, 1239–40, 1251–7, 1259, 1287. The dark lane not a practical danger, 1258–61; fine screening would not cause vessels meeting "green to green" to collide, 1262–9; screening should not be affected by dirt on the lens, 1275–7, 1288–92. Dimensions of lenses, 1239, 1241, 1269, 1271, 1280–3; colouring, 1270, 1288–95; oil usually burnt, 1303, 1314–6; angle at which wick is set, 1297–301, 1336–40; dimensions of wicks, 1302–3; position of wicks, 1304–5; triplex wicks, 1306; merits of electric light for side lights 1307–13. Screening from inside of wick preferable to outside, 1321–35; screening from the centre, 1341–7.

DEADMAN, Mr. H. E., Assistant to the Director of Naval Construction, 5463–569. Lights used in the Navy, 5480–91, 5511–5, 5568–9; electric light, 5481–90, 5559–60; how lights in the Navy are fixed, 5470–8, 5540–58; how they are screened, 5492–510, 5516–39, 5561–7; where they are placed, 5540–58.

DARK LANE, *Murray*, 4978–80, 185–202, 225–30. Its dimensions under different conditions, *Samson*, 370–400, 458–85, 642–60, App. 2, No. 14, App. 3, Nos. 1 and 2. Not a practical danger, *Hill*, 949; *Anderson*, App. 6, No. 1; *Corry*, 1258–61; *Colquitt*, 1390; *Posgate*, 1581, 1738–9; *Hogg*, 1774–5; *Little*, 1992–3; *Ruthven*, 2063; *Webster*, 2287; *Colomb*, 2572, 2651; *Chandler*, 2786–9, 2814–5; *Kendall*, 3365, 3371–4, 3482–6; *Noel*, 5269–74; *Keigwin*, 5428; *Edwards*, 5336–9. Smaller angle than 4° would produce a dark lane, *Tamlin*, 3947–64, 4057–73. Dangerous if no light crosses in front of the ship, *Mensing*, 3187–97, 3219.

DIRT ON THE LENS as affecting screening, *Samson*, 286–7, 354, 359, 361–2, 699–702; *Ramsay*, 718; *Corry*, 1275–7, 1288–92; *Hallett*, App. 20, No. 1.

DIFFUSED LIGHT. *See* REFLECTED LIGHT.

EDWARDS, Staff-Commander, R.N., 5278–413. Lights used in the Navy, 5281–2, 5313, 5391: electric lights work fairly well, 5311; wicks, 5314–8, 5386–90; how lights are fixed in the Navy, 5299–300; how they are screened, 5283–93, 5300A–5, 5342–58. Angle of 4° too large, 5294–8; it makes the field of mingled rays too wide, 5296–8, 5326–8; fine screening indicates change of course easily, 5330–1; lights should be screened by fixing the width of the field of mingled rays ahead of the ship, 5359–79, 5392–413; experience of dark lane, 5336–9; porting across the bow, 5326–8. Masthead light is sometimes placed too high, 5320–5; visibility of red and green lights, 5340–1, 5382–5.

ELECTRIC LIGHT. At present screened to outside of filament, *Samson*, 314–7. May be desirable to screen finer than oil lights, *Murray*, 5084–96, 5134A; *Anderson*, 1108, 1226–8; *Mensing*, 3273, 3320–33. Experiments in screening electric light, *Thomson*, 3495–510, App. 10; App. 12. Merits of electric light for side lights, *Corry*, 1307–13; *Wade*, 3834; good because it has no breadth, *Ruthven*, 2042; cuts cleaner than oil, *Chandler*, 2796; *Wade*, 3836–7. Special coloured shades required, *Murray*, 4881A–917, 5129–33, App. 13, No. 1; not necessary, *Harvie*, 3664–5; *see Ruthven*, 2191–201. Electric lights used in Navy, *Noel*, 5224–33; *Edwards*, 5306–12; *Keigwin*, 5433–6; *Deadman*, 5481–90, 5559–60. General evidence on use of electricity in side lights, *Hall*, 4466–586.

EXPERIMENTS with side lights. Reports of observations made in 1891, App. 2, Nos. 5 and 6. These experiments not exhaustive enough to justify the new rule, *Harvie*, 3541–50. Measurements made on S.S. "Ophir," *Ruthven*, 2167–9, App. 7, No. 1; on S.S. "Ireland," *Kendall*, 3337–8, 3404–15. Experiments made at Berlin, 3187, 3311–9, App. 8, Nos. 1, 2, and 3. Screening oil and electric lights at short distances, *Thomson*, 3495–525, App. 10. Screening common lamps, at about 1 sea mile, *Wilson Barker*, 4880–1, App. 11. Power of light at different points of lens with wick at different angles, *Harvie*, 3578–94, 3669–73, 3713–5, 3744. Screening oil lamps, at distances up to 2 miles in October 1893, App. 2, No. 11; in June 1895, App. 9. Screening electric lights at distances up to 2½ miles, App. 11. Effect of electric light on green glass, App. 13, No. 1.

FINE SCREENING.—Indicates change of course easily, *McDonald*, 2913–7, *Edwards*, 5330–1. Less alteration of course required to show one distinct light, *McDonald*, 2970, *Turriff*, 4371–3, 4379, 4394. Shows a ship which side she is on, *Wade*, 3812; makes Rule of the Road same for night as day, *Wade*, 3839.
*See also* under OBJECTIONS and SUGGESTIONS and OPINION.

FOREIGN SHIPS.—Angle to which they are screened, *Chalmers*, 897–9; App. 5. Nos, 1 and 2; *Hill*, 1059–60; German Lloyd, App. 2, No. 10; *Laslett*, 4650–2.

FOUR DEGREE rule, introduced in 1892. *Howell*, 38; App. 2, No. 1; *See* under HISTORY. Arguments in favour of, *Murray*, 44–238, 4881*a*–5134*a*, App. 2 and 13. Opinions of counsel as to its legality, *Howell*, 40, App. 1, No. 3. Opinion of Rule of the Road Committee, App. 1, No. 4. Was brought in to secure uniformity, *Samson*, 410–2; and adopted, after experiment, in preference to 3°, *ib.*, 486–8. It is desirable, because it gives full light ahead at a reasonable distance, and preserves the green to green rule, *Samson*, 264–81, 500–8, 649; it gives full light ahead at a reasonable distance, and allows for heeling, *Ramsay*, 758–62. What it means, *Samson*, 319, *Ramsay*, 816–27. Whether it causes unnecessary porting, *Samson*, 294–7; or uncertainty, *ib.*, 1070–5. Not a dangerous angle at sea, *Kendall*, 3342–54, 3402–3. Was not necessary, but has done no harm, *Colomb*, 2736. Reasons for approving 4°, *Mensing*, 3198, 3221–5, 3253–5, 3285–7. Smaller angle would give dark lane, *Tamlin*, 3947–64, 4057–73. Conditions at night not same as day, and lights must cross to enable ships to clear one another, *Richards*, 4219–37.
*See also* under OBJECTIONS and OPINIONS.

HALL, Mr. CHARLES, chief of the Repairs Department of the Peninsular and Oriental Company, 4465–586. Evidence as to electric side lights, 4466–586.

HARVIE, Mr. W., lamp manufacturer, 3526–749. Want of uniformity remarked in 1867, 3643; previous to 1892 his lights were fitted to about 2°, 3533–9, 3653–5; regarded old rule as practically meaning 2° from outside of wick, 3551–3, 3556–8; or 0° from inside, 3559–63, 3565; old rule was sufficient if properly carried out, 3643; inner edge of lens coincided with inner edge of wick, 3679–80. The 1891 experiments were not nearly exhaustive enough to justify the new rule, 3541–50; contrasts exhaustive trials made in Navy before lamps are received, 3544–7, 3612, 3615–20, 3623, 3749; the Board of Trade tests no tests at all, 3624–5, 3630–1, 3694. The 4° rule was accompanied by a compulsory change in the position of the wick, 3553–5, 3655, 3666–8, 3719–21; it increased length of lens, 3566–71; it really means 4⅓°, 3555, 3572–6; wider filament lamps substituted for narrower, 3601. Experiments show that it is impossible to get absolutely uniform light over the 10 points, but that the angle of the wick makes very little difference, 3578–94, 3669–73, 3713–5, 3744; angle of wick should not be fixed, as it changes with wear of burners, 3722. Lights should be screened from the focus, which will suit electric and oil equally, 3596–7, 3602–9; screening from outside of wick is a new idea, 3540; screening from the inside has advantage of simplicity, 3598–600. Visibility the essential requirement, 3527; difficulty with green lamp discovered before 1873, 3528–9; blue-green is the best colour, 3621–2; it serves equally for incandescent electric lamps and for oil lamps, 3664–5; a standard colour should be imperative, 3685. Price of lamps, 3628–9, 3647–50; copper better than iron, 3630; standard lamps, 3658, 3683–4, 3694, 3706. Solid lenses always defective, 3632; coloured shades preferable, 3640–2; lenses made singly, 3660–2; perfect lens is not luminous, 3674–6; fish-globe lenses, 3688–90; how made, 3728–33; dioptric lenses, 3737; lenses not needed with very powerful lights, 3743. Duplex burners recommended, 3707–12, 3716; they give same width of light as incandescent lamps, 3717–8; dimensions of reflectors, 3745–8. When light-towers were introduced, 3530; gimbals should not have been included in the Board of Trade Instructions, 3610–3, 3724–7; the Instructions require lamps to have too much vertical divergence, 3614, 3735–8.

HILL, Mr. A. N., Secretary of the Liverpool Steam Ship Owners' Association. 933-1061. Side-lights should be screened so as to minimise crossing, and the screening should be international, 938, 953-4, 980-7; most important that the lights should indicate change of course, 952; full light should be seen ahead, but this can be done without wide screening, 1029-46; majority of Association would screen to inner edge of wick, 1061; agrees that lights must cross, 1058. Objects to present rule because lights do not properly indicate position of vessel or change of course, 939; present rule is contrary to international regulations, 943-5, 955-60, 968; dark lane no danger, 949; present rule dangerous in narrow channels, 989-93, 1011-8, 1047-51; no advantage in having a wide field, 994-1000; everybody concerned objects to the present rule, 1047. Position of shipowners with regard to screening, 942, 970-80, 1018-27; a summary of their objections sent to Board of Trade, 962-7. Past practice was not uniform, 946-8; but new rule has increased the angle in many cases, 940-1, 950, 988, 1001-3, 1052-3; screening on foreign ships, 1059-60. Screening and the international regulations, 943-5, 955-60, 968, 1004-7, 1057.

HISTORY of the question of screening:

(1.) Prior to 1868.—History of the Rule of the Road so far as regards screening, *Colomb*, App. 21; history of side-lights prior to 1868, *Howell*, 6-21. The angle of screening contemplated by the old Admiralty regulations, *Samson*, 246-62, 304-10, 780-807, 413-24; text of these Regulations, App. 1, No. 1. Bad state of screening before 1868, *Colomb*, 2537-55, 2694, 2737-40, 2615-7.

(2.) 1868 to 1891.—Text of Board of Trade Instructions, 1868-91, App. 1, No. 2; origin of the Instructions of 1868, *Howell*, 22-37; the character of the Instructions of 1868-91, *Murray*, 55-71, 107, 5054-6, App. 2, No. 7. Discrepancy in Instructions of 1875, *Murray*, 61-9, 209, 5050-3; *Ramsay*, 737-42, *Chalmers*, 904; *Anderson*, 1103-4; *Corry*, 1239-40, 1251-7, 1259, 1287; *Colomb*, 2556, 2559; *Harvie*, 3551-65, 3679-80. Whether diagrams in the Instructions were drawn to scale, *Laslett*, 4737-51. Old rule was to screen to inner edge of lens, *Richards*, 4201-5, 4214-5; *Laslett*, 4631, 4849, 4858; *Taylor*, 5621, 5624-30, 5652-4.

(3.) How lights were screened previous to the 1892 Instructions (the 4° rule). How they would have been screened if the old Instructions had been complied with, *Murray*, 73-7, 105-7, 4920-3, 4941-7, 5057-9; measurements of lanterns, App. 2, No. 9, App. 4, No. 2; angle which would have been produced by old Instructions if lamps had been properly constructed, *Samson*, 287-91. How lights were actually screened, *Murray*, 78-80, 108, 4881*a*, 4969-70, 5111; *Samson*, 282-3, 322-3, 401-4, 410-2, 513; *Ramsay*, 708-18; *Chalmers*, 882-90. Summary of reports from Board of Trade officers, App. 2, No. 2; lists of ships inspected at London and Liverpool, App. 2, Nos. 7 and 8; at North Shields, App. 4, No. 1; at Greenock, App. 16. Cause of the variations, *Samson*, 284-91, *Laslett*, 4654-7, *Taylor*, 5616-37. New rule has increased the angle in many cases, *Hill*, 940-1, 946-8, 950, 988, 1001-3, 1052-3; *Colquitt*, 1377-81; *Anderson*, 1088-9, 1124, 1157-62, 1165-72, 1198-201, 1203-16. Actual effect of the new rule has been to increase the angle, *Ruthven*, 2065-7, 2106-8, 2180-5, 2201-3; *Webster*, 2264-9, 2352-3, 2457-8. Lights used to be screened anyhow, some to more than 4°, *Chandler*, 2773-4, 2854; some ships were more than 4°, others less, *Hubback*, 3027-30. City of Dublin steamers screened to about 4°, *Kendall*, 3361-4; Silvertown Company's ships varied from 2° to 5°, *Thomson*, 3511-9. Regarded old rule as meaning 2° from outside of wick, or 0° from inside, *Harvie*, 3551-65. Waterford Company's ships were screened to 0° from outside of wick, *Wade*, 3764-6, 3791-2, 3805, 3808-10; universal experience was that angle was increased, *Wade*, 3821. New rule made little or no difference, *Richards*, 4208-13, 4216-8, 4268-9, 4273-6, 4294-6. Before 1892 lights were screened finer, *Turriff*, 4368-9, 4401-6; own ship not altered, *Turriff*, 4412, 4434-5. Angle produced by old rule, *Laslett*, 4632, 4637, 4737; *Taylor*, 5571-600; effect of new rule on angle, *Laslett*, 4632-49, 4680-6, 4760-4, 4782-92, 4850-1. Sailors did not realise how lights were screened prior to 1892, *Colquitt*, 1428, 1513-5; *Hogg*, 1757-60, 1816; HISTORY of the question of screening—*cont.*
*Pusgate*, 1582-4, 1634, 1732-3; *Colomb*, 2578; *Chandler*, 2775-6; *Kendall*, 3359-60; *McDonald*, 2953-4; *Tamlin*, 3933, 3937; *Chapman*, 4099.

(4.) The 1892 Instructions.—Text of the 1892 Instructions, App. 2, No. 1. Origin of the 4° angle, *Murray*, 204-7, 4919, 4925-7, 4929, App. 2, Nos. 5 and 7; *Samson*, 410-2; *Anderson*, 1087, 1092-8, 1105-7, 1156, 1224, 1228. The Washington recommendation was made in error, *Ruthven*, 2029-30, 2240-52; was not an error, *Mensing*, 3173-86, 3265-9, 3298-310.

HOGG, Mr. T. T., Trinity House Pilot, 1748-963. Lights should be screened in line with the keel, 1761; it would be sufficient if they were screened to the inner edge of the wick, 1825-32, 1866-8, 1906, 1910, 1931-3; the full light should show ahead, and crossing should be minimised, 1764-6, 1814-5, 1856, 1933; screening should be done at night, 1780, 1939-42. Objects to 4° rule, because it may cause the wrong light to be seen alone if the other light is dim, 1763; the lights have a blinding effect on officers and look-out, 1763; the area over which all three lights are seen is too large, 1768-73; the lights give false indication, and make vessels port unnecessarily, 1770; vessels port unnecessarily as it is, 1834-9; crossing lights objectionable in narrow waters, 1795; how far screening effects narrow waters, 1804-13, 1862-4, 1870-5, 1895-905, 1945-52; dark lane not a practical danger, 1774-5; fine screening would not be dangerous for ships meeting nearly end on, 1781-4, 1840-8, 1884-94, 1954-61; extent to which vessels yaw, 1784-91, 1878-83; angle of list and its effect on the lights, 1792-4. Before 1892 considered lights generally did not cross, 1757-60, 1816; theory as to reflected light, 1763-73, 1849-52, 1915-21, 1934-6, 1953; want of uniformity in power of lights, 1795; 1859-60. Lights should be placed uniformly, abaft the foremast, 1796-1803; personally prefers them on the bridge, 1925.

HOWELL, Mr. W. J., principal clerk of Marine Department, Board of Trade. 1-43, App. 1. Duties of Board of Trade with regard to side-lights, 4-5. Sketch of history of side-lights prior to 1868, 6-21. Origin and character of instructions of 1868, 22-37. The 4° rule introduced in 1892, 38. Order in Council obtained to meet opposition, 39. Opinions of counsel as to legality of Order, 40. App. 1, No. 3. Opinion of Rule of the Road Committee as to its merits, 41, App. 1, No. 4.

HUBBACK, Captain L. B., 3016-3169. The angle of screening should be as small as possible, 3024-6, 3075; especially for narrow waters, 3035-41; not essential to have full light directly ahead, 3047; opinion of nautical men in favour of a small angle, 3045. Before 1892, some lights were screened to less than 4°, some to more, 3027-30; personally has had to alter chocks three or four times, in 1892 could see lights 18 feet forward of the lamps, 3031. Ships meeting nearly end on and screening, 3057-60, 3066-9, 3086-122; extent to which vessels yaw, 3049-50; rule to follow with yawing vessels, keep to the light which you get broad, 3069-70; would port to three lights 5° on the bow, 3082-5. Porting across the bows often occurs, 3071-4; dangerous to port across 4° at half a mile, 3124-6; with hand-gear it is more difficult to put the helm hard-a-starboard, 3080-1; 3139-41. Swinging davits are objectionable, 3043; a second mast-head light is not wanted, 3162-9. Lights should be placed in plane of or abaft the mast-head light, 3042, 3142-61; whether a fixed position would give any certain information, 3127-38.

INNER EDGE of wick. Merits of the inner edge as the point from which to screen, *Murray*, 4981-2, 5096; *Samson*, 581-622; *Corry*, 1321-35; *Mensing*, 3238-41, 3249-55; *Harvie*, 3598-600. Effect of screening to the inner edge, *German Lloyd*, App. 2, No. 10. *See also* under SUGGESTIONS.

INSPECTION of ship's lights. Necessarily insufficient and unable to secure uniformity, *Murray*, 48-9, 4982, 5045-9; more systematic tests desirable, *Murray*, 4909-17; how present tests are carried out, App. 13, No. 2; *Richards*, 4246-9, 4254-60, 4325-36. Impossible to check screening in merchant ships by observation, *Samson*, 495-9, *Richards*, 4250-3. Not many ships escape inspection, *Ramsay*, 866-9. Board of Trade tests no

INSPECTION of ships' lights—*cont.*
tests at all, *Harvie*, 3624–5, 3630–1, 3694; never knew Board of Trade to measure screening prior to 1892, *Wade*, 3807; inaccurate screening by Board of Trade, *Wade*, 3794–804. Inspection of lights in general, *Chalmers*, 912–14; *Laslett*, 4595–4600, 4653, 4664–78, 4684, 4709–31, 4765–81, 4859–73, 4876–7, 4806. Screening lights in towers, *Laslett*, 4793–4805; *Taylor*, 5655–8. Inspection of spare lights, *Richards*, 4261–5, 4297–305; *Laslett*, 4700–3. Inspection of colour of lens, *Richards*, 4306–13, 4337–8.

KEIGWIN, Staff-Commander, R.N., 5414–462. Lights used in the Navy, 5433–42; electric lights work well, 5433–6; how lights are screened, 5419, 5421–7. Four degree angle is too large, 5421; the finer lights are screened the better, 5445–6, 5455–60; never noticed dark lane, 5428. Ships meeting green to green and screening, 5447–56; porting across the bow, 5457–60.

KENDALL, Captain T. G., 3334–3494. Before 1892 never noticed anything wrong, 3358; seamen did not pay much attention to screening, 3359–60; own steamers were screened to very nearly 4°, 3361–4. Ascertained by experiment that lights showed beyond 4° when screened to that angle, 3337–8, 3404–15; and that 2° would answer all the purposes of the 4° angle, 3339–40; believes that the outside rays are lost at a distance of a mile, 3344–5; outside of lens is seen from stemhead, but no light that would be dangerous, 3379–81. Four degrees not a dangerous angle at sea, 3342–54, 3402–3; but 2° would answer all purposes, 3347–8; 3454–6. Attaches great importance to screening being uniform, 3357; screening should be left as it was prior to the Order in Council of January 1893, 3366, 3471–4; lights should be more powerful, and angle smaller, 3384–6, 3475–80. Dark lane is not a practical danger, 3365; least alteration of helm seems to shut out one light, 3371–4, 3482–6. Ships meeting nearly end on and screening, 3433–70, 3487–90; would port to 3 lights half a mile away 5 on the starboard bow, 3430–1. Visibility of side-lights, 3416–8; good green can be seen further than red, 3417–8; lights can be seen 4 or 5 miles off in exceptionally fine weather, 3492–4; his lights are on the paddle-boxes well abaft masthead light, 3375–8.

LASLETT, Mr. W. H., Board of Trade Surveyor, 4587–4879. Rule before 1892 to screen to inner edge of lens, 4631, 4849, 4858; angle produced by this rule, 4632, 4637, 4737; variations in screening under old rule, and their cause, 4654–7; effect of new rule on the angle of screening, 4632–49, 4680–6, 4760–4, 4782–92, 4850–1; more chocks deepened than cut down, 4638–9. The inspection of ships' lights, 4595–4600, 4653, 4664–78, 4684, 4709–31, 4765–81, 4859–73, 4876–7; difficulty in screening lights in towers 4793–805; laths or steel pipes preferable to tapes, 4806; inspection of spare lights, 4700–3; survey of lights on transfer to foreign flag 4650, 4687–92; the screening of foreign ships, 4650–2; how want of uniformity in screening is caused, 4654–63; prefers angling the screen to using a chock, 4812–5; the point to screen from should be the outer edge of wick, 4816. Meaning of uniform and unbroken light, 4874–5; whether the diagrams in the Instructions were drawn to scale, 4737–51. Whether a standard lamp is desirable or practicable, 4816–44. Size of lamps, 4826–31, 4878–9; triplex wicks rare, 4704; variation in position of wicks, 4845–8, 4852–8; gimbals not often seen, 4705–8; length of screens, 4749–54; screens liable to bend, 4807–11. Opinion as to position of lights, 4693–99; Board of Trade do not insist on lights being put forward, 4626–31, 4755–9.

LENSES. In general, *Samson*, 449–52, 676; should be not less than 130°, *ib.*, 432; should be more than 10 points, *Colomb*, 2654–63. Their dimensions *Corry*, 1239, 1241, 1269, 1271, 1280–3; their colouring, *ib.*, 1270, 1288–95. Effect of the lens, *Mensing*, 3194; luminosity of the lens, *ib.*, 3276–80. Solid lenses always defective, and coloured shades preferable, *Harvie*, 3632, 3640–2. Lenses made singly, *Harvie*, 3660–2; dioptric lenses, *ib.*, 3737; fish-globe lenses, *ib.*, 3688–90, 3728–33, *Ramsay*, 838–42. Perfect lens is not luminous, *Harvie*, 3674–6. Board of Trade Instructions as to lenses, App. 2, No. 1, par 9.

LIGHTS.—Whether it is possible to secure uniform light over 10 points by the mere construction of the lantern, *Murray*, 101–4, 4948–56; *Samson*, 331–69. Diversity of patterns as affecting screening, *Murray*, 50–3; German Lloyd, App. 2, No. 10; Measurements of different lanterns, App. 2, No. 9, App. 4, Nos. 2 and 3. Usual construction of side-lights, *Ramsay*, 719–35, 743–57. The kind usually employed, *Corry*, 1303, 1314–6; *Scrutton*, 1354; *Mensing*, 3261; *Richards*, 4250, 4253. Their size, *Laslett*, 4826–31, 4878–9. Their price, *Harvie*, 3628–9, 3647–50. In some lamps the housing covers the wick, *Taylor*, 5644–6. Reports on lights at various ports by sub-committees, App. 20.

LIST.—How it affects screening, *Ramsay*, 763–79, 859–65. Its extent, *Colquitt*, 1533; *Hogg*, 1792–4. It would not affect the appearance of lights, *Chandler*, 2798–801.

LITTLE, Mr. G. H., 1964–2014. Lights should be screened to cross as little as possible, 1976–77; they always have crossed and must cross, 1969; would place the lights amidships, back to back, 1994–7, 2001–11; a uniform light should be seen ahead, 1998. Objects to 4° rule because the two lights seen ahead lose their distinctive value, 1975; the dark lane is not a practical danger, 1992–3.

MCDONALD, Captain D., Clyde River Pilot, 2860–3015. Represents Clyde River Pilots, 2875. Character of navigation in the Clyde, 2876, 2933–40, 2960–6, 2972–5, 3013–5; how far screening affects narrow channels, 2878–9, 2887–92, 2940–5; navigation in narrow channels assisted by fine screening, 2948–9. Lights should be screened as finely as possible, 2877, 2971; fine screening would not make it doubtful what the other ship was going to do, 2913–7; would not lead to close shaves, 2923; would enable pilots to keep their position in river and lose sight of other ship's green light quickly, 2970; fine screening has no disadvantages, 2971. Instances of danger caused by 4° screening, 2878, 2956–7, 2959; vessels appear to be crossing when they are on parallel courses, 2878; navigation is safe in spite of the 4° rule, because other lights are seen, 2879, 2969; 4° not so objectionable in open sea, 2921, 2967; even there would prefer fine screening, 2951–2. Ships meeting nearly end on and screening; would port to three lights 5° on starboard bow, 2898–902. Before 1892 thought lights screened to inside of wick, 2953; but knew some light crossed, 2954; has not noticed any difference in lights since 1892, 2897; believes angle was increased in some cases, 2896. Effect of right hand propellers on helm, 2903–11, 2925–7, 2976–80; whether it is harder to give port or starboard helm with hand steering gear, 2981–3012.

MENSING, Captain A., of the Imperial German Navy, 3170–3333. The angle of screening recommended by the Washington Conference, 3173–78, 3180–3, 3265–9, 3298–310; the recommendation was not a blunder, 3183–6. Experiments in screening at Berlin described, 3187, 3311–9. Dangerous to screen so that no light crosses because the two lights are not seen together, 3187–97; yawing does not obviate the danger, 3197; the regulations require both lights to be seen together at 2 miles, 3283, 3290–7; the ordinary dark triangle is no danger, 3219. Reasons for approving 4°, 3198, 3225, 3253, 3255, 3285–7; that is, 4° measured from the flame, 3221–4; no angle smaller than 2·8 degrees need be considered, 3200; light seen from stemhead is weak and caused by reflection, 3272. How the chock acts in cutting off the flame, 3243–7; screening from the inner edge of the wick, 3238–41, 3249, 3255. Lamps should always be in focus, 3261; uniformity of lanterns of doubtful value, 3258–63; existing varieties, 3264; the effect of the lens, 3194; luminosity of the lens, 3276–80; visibility of side-lights depends on the colouring, 3281. Electric light should be screened in the same way as oil, 3273; finer screening might be admissible so long as it produced the same field, 3320–33. Nearly end on, about 4° or 5°, 3284; this angle should correspond with the angle of screening, 3285–7.

MURRAY, Sir Digby, Bart., Professional Officer, Marine Department, Board of Trade, 44–238, 4,881*a*–5134*a*; Appendices 2 and 13. Powers of Board of Trade limited, 45–53, 233–4; their main object with regard to side-lights, 54, 81, 108.

MURRAY, Sir Digby, Bart.—*cont.*
Screening instructions from 1868 to 1892 described, 55–71, 5054–6; they were only recommendations, 107. Error in instructions of 1875, 61–9, 209, 5050–3. Angle prescribed by instructions previous to 1892, 73–77, 105–7, 4920–23, 4941–7, 5057–9. App. 2, No. 9. Angle to which vessels were actually screened prior to 1892, 78–80, 108, App. 2, Nos. 2, 7, 8, 4881*a*, 4969–70, 5111. Washington Conference and origin of the 4° angle, 204–7, 4919, 4925–7, 4929, App. 2, Nos. 5 and 7. Instructions of 1892, 72, App. 2, No. 1. The report of the Rule of the Road Committee on screening, 4984–88, 4992*a*. Effect of new rule—alteration in position of wick, 77, 102, 231–8. The Regulations and their meaning, App. 2, No. 7. Right ahead, 82–6, 5063–6. "Across the bow," 87–9. "Nearly end on," 4931–40. Unbroken light over 10 points incompatible with lights not crossing, 90–8. Impossible to secure uniform light over 10 points by the construction of the lamp alone, 101–4, 4948–66. Arguments in favour of the 4° angle;—Ships which are approaching nearly end on may collide if they are too finely screened, 113–139, 4931–40, 5000–9, App. 2, No. 4, No. 13, C. 4° screening not dangerous, even when ships are 4° on each other's starboard bow, 140–78, 5010–38, App. 2, No. 13, B. *See also* App. 13, No. 3. Sound signals can be used when vessels are in sight of one another, 5117–23, 5134. Effect of screening lights so that they do not cross at all, 185–202; "dark lane," 185–202, 225–30, 4978–80. Yawing unreliable as a defence of fine screening, 203, 5037–8, 5068–73. 4° screening is not specially unsafe in narrow waters, 4993–7. Extent to which reflected light is seen, 184; lights seen on the forecastle, 5060–2. Objections to screening to inner edge of wick, 4981–2, 5096. Remarks on the opinions expressed by masters and pilots, 5105–10, App. 13, No. 2. The essential thing is uniformity, 5077–100; uniformity in the dimensions of the field covered by both lights, 5078, 5134; a finer screening may therefore be necessary for electric light, 5084–96, 5134*a*. It is desirable to have a standard lamp, 235, 5049. At present uniformity is prevented by diversity of lamps, 50–53; different conditions of wick also cause different results, 4992, 4997–8, 5084–96. Present system of inspection cannot secure absolute uniformity, 4982, 5045–9. More systematic tests desirable, 4909–17. Evidence as to special shades for electric light, 4881*a*–4917, 5129–33, App. 13, No. 1. Difference between the red and green lights, 4989–92, App. 2, No. 13, A. Remarks on the Committee's experiments, 4977, 4983. Position of lights;—uniformity impossible, 5039–44; prefers lights on bridge, 5043; present rule, 5060–1. Additional masthead or danger light suggested, 178, 212–24; general conclusions, App. 13, No. 2.

NARROW WATERS. How far navigation in narrow waters is affected by screening, *Murray*, 4993–7, App. 13, No. 2; *Samson*, 319, 509–11, 624–5; *Hill*, 989–93, 1011–8, 1047–51; *Hogg*, 1804–13, 1862–4, 1870–5, 1895–905, 1945–52; *Tamlin*, 4037; *McDonald*, 2878–9, 2887–92, 2940–5.
*See also* under COLQUITT, HOGG, MCDONALD, POSGATE.

NAVY. Exhaustive trials made before lights are received, *Harvie*, 3544–7, 3612, 3615–20, 3623, 3749. Lights used, *Phillips*, 5140–1; *Noel*, 5213–8, 5,224–33; *Edwards*, 5281–2, 5311, 5313, 5391; *Keigwin*, 5433–42; *Deadman*, 5480–91, 5511–5, 5568–9, 5559–60. How lights are fixed, *Phillips*, 5142–52; *Noel*, 5219–20; *Edwards*, 5299–300; *Deadman*, 5470–8, 5540–58. How screened. App. 14, No. 13; *Phillips*, 5153–83, 5187, 5195–7; *Noel*, 5234–8; *Edwards*, 5283–93, 5300*a*–5, 5342–58; *Keigwin*, 5419, 5421–7; *Deadman*, 5492–510, 5516–39, 5561–7. *See also* Appendices 14 and 15.

NEARLY END ON. Ships meeting nearly end on and screening. (1) Whether fine screening causes danger. Ships approaching green to green may collide if they are finely screened, *Murray*, 113–39, App. 2, No. 4, 4933–40, 5000–9, App. 2, No. 13, C. Angle of screening should coincide with angle of nearly end on, *Murray*, App. 13, No. 2; *Samson*, 685–9; *Mensing*, 3284–7; conditions at night not the same as those in daytime, *Murray*, App. 13, No. 3. Whether it is safe to starboard to a green light, *Murray*, App. 13, No. 2. Green to green

NEARLY END ON—*cont.*
argument further stated, *Samson*, 268–79, 294–301, 544–57, 690–8. Fine screening would not cause danger, *Anderson*, 1145–55, 1163–4, 1173–82; *Corry*, 1262–9; *Colquitt*, 1363–76; *Posgate*, 1,585–94, 1659–67, 1691–701; *Hogg*, 1781–4, 1840–8, 1884–94, 1951–61; *Ruthven*, 2103–5, 2109–11, 2133–52, 2170–1, 2218–38, 2253–5; *Webster*, 2279–86, 2292–312, 2317–36, 2339–40, 2419–43, 2459–73, 2475; *Colomb*, 2582–614, 2670, 2683–92, 2696–709, 2751–61; *Chandler*, 2817–28, 2831–4, 2843–5; *McDonald*, 2913–7, 2923; *Hubback*, 3057–60, 3066–93, 3086–122; *Kendall*, 3433–70, 3487–90; *Wade*, 3813–8, 3859–60; *Chapman*, 4090–2, 4133–42; *Turriff*, 4378–9; *Phillips*, 5189; *Noel*, 5242–51; *Keigwin*, 5447–56. Would screen without reference to the angle of nearly end on, *Colomb*, 2623–32. (2) Whether 4° screening causes danger. It is not dangerous for two ships 4° on each other's starboard bow to port, *Murray*, 140–78, 5010–38, App. 2, No. 13, B., App. 13, No. 3; *Chalmers*, 915–22. Would have to port to three lights 4° on the starboard bow at half a mile, but it would be dangerous, *Webster*, 2518–29; *Hubback*, 3082–5, 3124–6; it would be a mad thing to do, *Colomb*, 2664–71; would port to three lights 5° on the starboard bow, *McDonald*, 2898–2902; *Kendall*, 3430–1; *Tamlin*, 3992; would port to a green light, *Tamlin*, 3933–4002, 4018–21. Porting across the bow, *Phillips*, 5190–4; *Edwards*, 5326–8; *Keigwin*, 5457–60; *Noel*, 5252–8, 5260–8. Effect of right hand propellers on helm, *McDonald*, 2903–11, 2925–7, 2976–80. Whether it is harder to give port or starboard helm with hand steering gear, *McDonald*, 2981–3012; *Hubback*, 3139–41.

NOEL, Commander, R.N., 5209–5277. Lamps used in the Navy, 5213–8; electric light, 5224–33; how they are fixed, 5219–20; how screened, 5234–8. Lights should be screened finer than 4°, 5240–1; never seen a dark lane, 5269–74. Ships meeting green to green and screening, 5242–51; porting across the bow, 5252–8; tactical circle of "Royal Sovereign," 5260–8.

OBJECTIONS to the 4° angle. The lights give misleading information. Position of a vessel is not properly indicated, this is especially dangerous in narrow channels, *Hill*, 939, 989–93, 1011–8, 1047–51; *Anderson*, App. 6, No. 1; *Colquitt*, 1362, 1382–4, 1386–9; *Posgate*, 1575–9, 1651–6, 1702–5, 1725–31, 1743–6; *Hogg*, 1768–73; Trinity House Pilots, App. 6, No. 2; *McDonald*, 2878. *Ruthven*, 2038, 2043–51, 2270, 2276, 2340, 2386–99. Wrong light may be seen alone, *Posgate*, 1574, 1578–9, 1678; *Hogg*, 1763; *Webster*, 2338; *see Colomb*, 2573, 2637, 2709. Meeting a number of ships in narrow waters it may be necessary to port to all of them, *Wade*, 3767, 3840, 3876. Both lights can be seen although a ship is going clear, *Wade*, 3770, 3862. Ships are forced to port unnecessarily across one another's bows, *Chapman*, 4108–16. Uncertainty is caused as to what a ship is going to do, *Turriff*, 4398–400. Instances of danger caused by screening, *Anderson*, 1187–97, App. 5, No. 3; *Posgate*, 1709; *Ruthven*, 2052–8; *Webster*, 2338; *McDonald*, 2878, 2956–7, 2959. Lights have a blinding effect on officers and look-out men, *Hogg*, 1763; they can be seen from forward, *Ruthven*, 2129–32; *Webster*, 2345–8; *Chandler*, 2787; *Hubback*, 3031; *Wade*, 3766, 3793–4, 3905–7. Light seen from forward is weak and caused by reflection, *Mensing*, 3272; outside of the lens can be seen, but no light that would be dangerous, *Kendall*, 3379–81. *See also Murray*, 5060–2.

OPINIONS OF MASTERS AND PILOTS on the question of screening. Everybody concerned objects to the 4° rule, *Hill*, 1047; nautical opinion unanimous against it, *Ruthven*, 2061; *Hubback*, 3045; *Wade*, 3830–1; nautical opinion would be satisfied with screening to inner edge of wick. *Chapman*, 4103; coasting opinion in favour of finer screening than 4°, *Turriff*, 4387–8, 4413–9, 4421. *See also Murray*, 5105, App. 13, No. 2; *Samson*, 320, 499; and under SHIPOWNERS.

PARALLEL SCREENING. Effect of screening to 0° from the outer edge of the wick, i.e., so that lights do not cross at all, *Murray*, 185–202, 225–30, 4978–80; *Samson*, 263, App. 2, No. 14; *Mensing*, 3187–97; 3283, 3290–7.

PHILLIPS, Staff-Captain, R.N., 5135–208. Lamps used in the Navy, 5140–1; how they are fixed, 5142–52; how screened, 5153–83, 5187, 5195–7; screens are used abaft the beam, 5159, 5180. Advocates moderate screening, 5184–5; 4° is too coarse, 5186, 5194; parallel screening too fine, 5187. Ships meeting green to green and screening, 5189; porting across the bow, 5190–4. The red light can always be seen before the green, 5200.

POSGATE, Mr. J. T., Trinity House pilot, 1548–747. Lights should be screened as fine as possible, about 1° from outside of wick, 1561–73, 1706–8, 1643–7, 1657–8; full light should be seen ahead at any rate with sailing vessels, 1580, 1626–33; there should be uniform fine screening for sea and river work, 1732–7; especially important that screening should be fine in narrow waters, 1575–9, 1651–6, 1702–5, 1710, 1725–31. Objects to 4° rule because it is misleading, a ship on the starboard bow sees the port light, 1574, 1578–9, 1678; the 4° rule has caused uncertainty, 1743–6; uncertainty a cause of collisions, 1718; instance of danger caused by screening in the Thames, 1709; evidence as to navigation in narrow channels, 1604–25, 1668–87, 1740–3; dark lane not a practical danger, 1581, 1738–9; its non-existence would show that lights crossed, 1648–50; fine screening would not be dangerous for ships meeting green to green, 1585–94, 1659–67, 1691–701; extent to which vessels yaw, 1595–601; side-lights sometimes visible 5 miles, 1581. How lights were thought to be screened before the new rule, 1582–4, 1634, 1732–3. Side-lights should be placed the width of the ship ahead of the masthead light, 1721–4.

POSITION OF LIGHTS. Side-lights should have a uniform position abaft the masthead light, *Anderson*, App. 6, No. 1; *Hogg*, 1796–803, 1925; *Ruthven*, 2085, 2117–24; *Webster*, 2341–4, 2263–9, 2398, 2492–2502, 2511–7; *Turriff*, 4444–58; *Wade*, 3790, 3825–6, 3880–2, 3888–904; in plane of or abaft masthead light, *Hubback*, 3042, 3142–61; the position should be uniform, *Shipmasters' Society*, App. 17, No. 1. Position should be uniform ahead of masthead light, *Posgate*, 1721–4; uniform position difficult to attain, but lights should be placed foward, *Chapman*, 4174–200. Whether uniformity of position is possible, *Murray*, 5039–44; value of fixing the position uncertain, *Colomb*, 2714; *Hubback*, 3127–38. Present rule and practice of the Board of Trade, *Murray*, 5060–1, App. 2, No. 1, par. 16; *Samson*, 311; *Wade*, 3879; *Laslett*, 4626–31, 4755–9.

RAMSAY, Mr. J., Principal Officer of Board of Trade for North-Eastern District, 703–869, App. 4. Screening prior to 1892, 708–42, 829–37, 866–69, App. 4, Nos. 1 and 2. Lanterns and lenses, 743–57, 838–40, App. 4, No. 3. Reasons for approving screening to 4°, 758–79, 799–808. Lights were always meant to cross, 780–98, 843. Seamen did not know that lights crossed, 809–10. Answers to objections to 4° angle, 811–27. Meaning of the regulations, 844–58. Screening as affected by heeling, 762–79, 859–65. Angle of screening on foreign ships, App. 5, No. 2.

REFLECTED LIGHT. Extent to which it is seen, *Murray*, 184; *Samson*, 274–5; *Hogg*, 1768–73, 1849–52, 1915–21, 1934–6, 1953; *Ruthven*, 2186–9; *Webster*, 2477–91; *German Lloyd*, App. 2, No. 10. Lights screened to 4° show beyond that angle, but outside rays are lost at no great distance, *Kendall*, 3337–8, 3344–5, 3404–15. *See also* reports of Captain Thomson's experiments, App. 10; and the Committee's experiments, App. 9 and 12.

REGULATIONS FOR PREVENTING COLLISIONS. Text of the Order in Council of January, 1893, App. 2, No. 12; whether it constituted an alteration of the regulations, *Samson*, 661–8; *Hill*, 943–5, 955–60, 968, 1004–7, 1057. Opinion of Counsel and of the Law Officers of the Crown, App. 1, No. 3. Meaning of "right ahead," *Murray*, 82–6, 5063–6, *Ramsay*, 844–58; *Chalmers*, 878–81, 900–2; *Colquitt*, 1479–84; *Colomb*, 2618–22; *Wade*, 3887; *Tamlin*, 3934, 3938–9, 3969; App. 6, No. 1. "Nearly end on," *Murray*, 4931; *Wade*, 3857–8. "Across the bow," *Murray*, 87–9; *Samson*, 302–4; *Colquitt*, 1379–80; *Wade*, 3775–886. Uniform light over 10 points incompatible with lights not crossing, *Murray*, 90–8. Whether uniform light over 10 points is secured, *Samson*, 682–4; *Harvie*, 3578–94, 3669–73, 3713–5, 3744. Whether it is possible to secure uniform light over 10 points by the mere construction of the lantern, *Murray*, 101–4, 4948–66; *Samson*, 331–69.

RICHARDS, Mr. T. J., Board of Trade Surveyor, 4200*a*–338. Before 1892 rule was to screen to inner edge of lens, 4201–5, 4214–5; new rule made little or no difference in the screening, 4208–13, 4216–8, 4268–9, 4273–6, 4294–6. Approves of 4° angle because conditions at night are not same as during day, and lights must cross to enable vessels to clear one another, 4219–37. How screening is verified, 4246–9, 4254–60, 4325–36; lights cannot be tested as to visibility, 4250–3; extent to which spare lamps are inspected, 4261–5, 4297–305; extent to which colour of lens is tested, 4306–13, 4337–8. Quality of lamps in use, 4250, 4253; position of wick with regard to screen varies greatly, 4239–41; position of wick in lamp, 4242–3, 4319–23; width of wick, 4285–7.

RUTHVEN, Captain J. Fitz-G., 2015–255. How lights were screened under the old rules, 2034, 2036, 2095–102; origin of the new rules, the Washington recommendation was an error, 2029–30, 2240–52; it was restrictive, while the Board of Trade rule is compulsory, 2059–60; protested against new rule in 1892, 2017–20; the actual effect of the new rule has been to increase the angle, 2065–7, 2106–8, 2180–5, 2201–3; vessels on his starboard bow have since ported across his bow, 2021–2. Objects to the new rule because of the large area of the field covered by powerful lights, 2038, 2043–4, 2046–9; this is especially objectionable in narrow waters, 2049–51, 2116; instances of danger caused by screening, 2052–8; nautical opinion unanimous against the new rule, 2061; argument that both lights must be seen close ahead in fog invalid, 2062, 2239; dark lane not a practical danger, 2063; side-lights can be seen from stemhead, 2129–32. Lights should be screened to the smallest angle which will allow them both to be seen together ahead, 2026; the power should be increased and the angle reduced, 2125; suggests 1° from centre of wick, 2064; this angle satisfies the Regulations, 2069, 2153–6; full light ahead at short distances not indispensable, 2027–8, 2045, 2094; uniformity desirable but lights must not cross, 2039–41; fine screening enables side-lights to fulfil their purpose, *i.e.*, indicate change of course and permit rule of the road to be carried out by night as well as by day, 2084; increase in size and speed of ships has made screening more important, 2032–3. Ships meeting nearly end-on and screening, 2103–5, 2109–11, 2133–52, 2170–1, 2218–38, 2253–5; yawing and screening, 2112–5. Electric lights good because they have no breadth, 2042; electric lights and colour of green light, 2191–201; lamps should be uniform, 2086–90; position and angle of wicks, 2172–5. Screening the light abaft the beam, 2156–66; measurements of actual screening and crossing point, 2167–9; diffused light, 2186–9; screening from centre of wick as opposed to screening from outside or inside, 2204–17. Position of lights should be uniform, 45° abaft masthead light, 2085, 2117–24.

SAMSON, Mr. P., Principal Assistant to Engineer Surveyor in Chief, Board of Trade, 239–702, 1062–79, App. 2, No. 14, App. 3. The early Regulations and screening, 246–62; how lights were placed originally, 304–10; screening was probably very broad before chocks were introduced, 413–24; angle which would have been produced by old instructions if lamps had been properly constructed, 287–91; how lights were screened prior to 1892, 282–3, 322–3, 401–4, 410–2, 513–39; why the screening was not uniform, 284–91; the 4° angle was brought in to secure uniformity, 410–2; it was adopted after experiment in preference to 3° 486–8. Four degree rule desirable because it gives full light at reasonable distance ahead and preserves the green-to-green rule, 264–81, 500–8, 649; screening does not affect narrow waters, 319, 509–11, 624–5; cause of opposition to 4° rule, 320, 499; with powerful narrow wicks angle might be reduced, 313; screening abaft the beam not necessary, 457–8; screening from the outside of wick as opposed to screening from inside, 581–622. Green-to-green argument stated, 268–79, 294–301, 544–57, 690–8;

Samson, Mr. P.—*cont.*
whether 4° rule causes unnecessary porting, 294–7; whether it causes uncertainty, 1070–5; what the 4° angle means, 319; angle of screening should coincide with angle of nearly end on, 685–9; screening only affects rule of the road when ships are meeting nearly end on or overtaking, 1076; whether screening is more important at long or short distances, 1077–9. Width of field of mingled rays with different angles of screening, 627–31, App. 3, No. 1; point at which rays cross under different conditions, 370–400, 458–83, 642–60; dark triangle, 484–5, 657; actual as compared with calculated distances, 271–5, App. 3, No. 3; experiments at Shoeburyness in 1891 and 1893, 558–79. Whether Order in Council altered the regulations, 661–8; meaning of across the bow, 302–4; uniform light over the 10 points attainable, 682–4; whether it is possible to secure this uniform light over the 10 points by the mere construction of the lantern, 331–69; why screens were added, 358–69. Width of wicks, 313, 324–30; their position, 669–75; wicks should be at right angles to the keel, 438–48; and be at the centre of curvature of lens, 447; lenses, 449–52, 676; should be not less than 130°, 432; dirt on the lens as affecting screening, 286–7, 354, 359, 361–2, 699–702; reflected light, 274–5; visibility of lights, 277–9, 490–4; electric light screened to outside of filament, 314; diameter of filament, 315–7. Impossible to check screening in merchant ships by observation, 405–9. Lights sometimes carried abaft the beam; Board of Trade endeavour to put them forward, 311.

Screens.—Why they were required, *Samson*, 358–69. Their length, *Chalmers*, 896; *Laslett*, 4749–54; *Taylor*, 5616–9, 5652–4. They are liable to bend and not always parallel to the keel, *Taylor*, 4807–11, 5587. Requirements of the Instructions, App. 2, No. 1, par. 16.

Scrutton, Mr. T., a member of the Committee, 1354. Description of lamps usually employed in the Merchant Service, 1354.

Shipowners.—Their position with regard to screening, *Hill*, 942, 970–80, 1018–27; *Anderson*, 1084–94, 1097–9, 1198–9, App. 6, Nos. 1 and 3. Letters giving opinions of shipowners, App. 19.

Standard Lamp.—Necessary that lamps should be of uniform pattern, *Murray*, 235, 5049; *Anderson*, 1099; *Ruthven*, 2086–90; *Webster*, 2400–2, 2530; *Chandler*, 2835–7; *Taylor*, 5638–42; German Lloyd, App. 2, No. 9; Shipmasters' Society, App. 17, No. 7. *See also Colomb*, 2747–8; and *Harvie*, 3658, 3683–4, 3694, 3706.

Suggestions as to how lights should be screened. Lights should be screened as finely as possible, *Hill*, 938, 953–4, 980–7; *Anderson*, 1102; *Colquitt*, 1360–1, 1392–9, 1433–4; *Little*, 1976–7; *Posgate*, 1561–73, 1643–7, 1657–8, 1706–8, 1732–7; *Webster*, 2271, 2277, 2784–5; *McDonald*, 2877, 2971; *Hubback*, 3024–6, 3035–41, 3075; *Tamlin*, 4050–6; *Keigwin*, 5445–6, 5455, 5460. They should be screened finer than 4°, especially in narrow channels, *Turriff*, 4363, 4370, 4373–6, 4379, 4389–96; finer than 4°, *Phillips*, 5184–7, 5194; *Noel*, 5240–1. No degrees from the outside of wick, *Wade*, 3772, 3805, 3832, 3866–9, 3919, 3870–3. Smallest angle which will allow both lights to be seen together ahead, *Ruthven*, 2026, 2064, 2069, 2153–6. Inner edge of the wick suggested, *Anderson*, 1103, 1109–11, 1113–18, 1134–42, 1221–4; *Corry*, 1239–40, 1251–7, 1259, 1287; *Hogg*, 1761, 1825–32, 1866–8, 1906–10, 1931–3; *Colomb*, 2563, 2575–7; *Chapman*, 4092, 4117–23, 4103. Lights should be screened to the centre of the wick, *Chandler*, 2770, 2780–1; they should be screened from the focus, *Harvie*, 3596–7, 3602–9. Angle of two degrees would answer all purposes; the lights should be made more powerful and the angle reduced, *Kendall*, 3366, 3384–6, 3471–80; with powerful narrow wicks angle might be reduced below 4°, *Samson*, 313. No angle smaller than 2·8 degrees need be considered, *Mensing*, 3200. Screening should be done at night, *Webster*, 1780, 1939–42. Angling the screen is a better method than using a chock, *Laslett*, 4812–5. The full light should be shown ahead, *Hill*, 1029–46; *Anderson*, 1102; *Colquitt*, 1431–2, *Posgate*, 1580, 1626–33; *Hogg*, 1764–6, 1814–5, 1856, 1933; *Little*, 1998; *Chandler*, 2810–3. Full light directly ahead not indispensable, *Ruthven*, 2027–8, 2045, 2094; *Webster*, 2272–5, 2301–6 *Colomb*, 2570; *Hubback*, 3047.

Tamlin, Mr. D., Swansea Pilot, 3928–4073. Before 1892 understood little about screening, 3933; astonished to find screening had not been uniform, 3937; screening was more than 4° 23 years ago, 3940–6. Approves 4° angle because smaller angle would produce a dark lane, 3947–64; views as to dark lane, 4057–73; sufficient if full light is seen ahead a mile distant, 3970; agrees that angle should be as small as possible, 4050–6. Meaning of right ahead, 3934, 3938–9, 3969; would port to three lights half a point on the bow, 3992; would port to a green light, 3993–4002, 4018–21; whether screening affects narrow waters, 4037.

Taylor, Mr. T. D., Board of Trade Surveyor, 5570–5658. Rule as to screening before 1892, 5621–30, 5652–4; how ships were screened before 1892, list of 100 ships inspected, 5571–5600, App. 16; how want of uniformity was caused, 5616–37. Screens not always parallel to keel, 5587; length of screens, 5616–19, 5652–4; screening lights in towers, 5655–8. A standard lamp desirable, 5638–42; in some lamps the housing covers the wick, 5644–6. Position of masthead light, 5601–15, 5647–51.

Thomson, Captain A. S., a Member of the Committee, 3495–3525, Appendix 10. Describes experiments made to determine the extent to which electric light affects screening, and the angle at which the extreme outer rays cross at short distances, 3495–3510; general outcome of the experiments, 3520–5. How vessels of Silvertown Telegraph Company were screened prior to the new rule, 3511–19.

Turriff, Captain, Master Mariner, 4339–4464. Before 1892 lights were screened finer, 4368–9, 4401–6; understands that position of wicks varied, 4385; own ship was not altered, 4412; his lights are now at 4°, 4434–5; the effect of the 4° rule was to cause uncertainty as to what a ship was going to do, 4398–4400, 4404–6; both side lights seen from forward, 4407, 4429–33, 4439–43. Lights should be screened finer than 4°, 4363; especially in narrow channels, 4370, 4373–6, 4379, 4389–96; angle of 2° suggested, 4383; fine screening would do for sea-work also, 4396, 4427; navigation in narrow channels, 4370, 4373–82, 4422–8, 4459–64; the advantage of fine screening is that less alteration of course is required to show one distinct light, 4371–3, 4379, 4394; coasting opinion is in favour of finer screening, 4387–8, 4413–9, 4421. Ships meeting green to green and screening, 4378–9. Lights should be placed abaft the foremast, 4444–58.

Wade, Captain W. S., Master Mariner, 3750–3927. Until recently lights were screened parallel to the keel, 3763, 3883–5; Waterford Company's ships were screened to 0° from outside of wick, 3764–6, 3791–2, 3805, 3808–10; universal experience was that chocks were cut down, 3821; never knew Board of Trade to measure screening prior to 1892, 3807; inaccurate screening by Board of Trade, 3794–3804. Objects to 4° rule because in narrow waters a ship may be put ashore before she shuts in green light, 3767; meeting a number of vessels in narrow waters it may be necessary to port for them all, 3767, 3840, 3876; there is a danger of one porting while the other starboards or keeps her course, 3767; both lights can be seen even when vessels are going clear, 3770, 3862; the lights can be seen on the forecastle, 3766, 3793–4, 3905–7; present screening seems to affect the apparent height of the lamps, 3789; the dark lane not a serious danger, 3775; extent to which a ship deviates from her course, 3776–88, 3822–4, 3923–7; never heard anyone speak in favour of the 4° rule, 3830–1. Lights should be screened to 0° from outer edge of wick, 3772, 3805, 3832, 3866–9, 3919; this screening has been proved to be safe, 3870–3; fine screening shows a ship at once which side she is on, 3812; it makes the rule of the road the same for night as day, 3839. Meaning of across the bow, 3775, 3886; half a point on the bow is nearly end on, 3857–8; meaning of right ahead, 3887. "Green to green" rule and screening, 3813–8, 3859–60. Electric light not so good as oil in hazy weather, 3834; it cuts cleaner than oil, 3836–7; lamps should be uniform, 3773; standard lamp, 3833–5, 3863. Lights should be placed amidships abaft the masthead light, 3790, 3825–6, 3880–2, 3888–3904; they should not be placed on the forecastle, 3842–50, 3878–9, 3888; Board of Trade always place them forward. 3879.

WEBSTER, Captain, M.P., 2256–2530. Before the new rule lights were screened in line with the keel, 2264–8, 2361–2, 2370–85, 2444–8; new rules made a marked change, quotes case of danger caused by wrong light being seen alone, 2338; new rule increased the crossing of the lights, 2269, 2457–8; in own line angle was increased, and the Board of Trade statistics are incomplete, 2352–3; old lenses rendered insufficient by the new rule, 2354–7; Board of Trade not sufficiently practical, 2358–9. Objects to the 4° rule, because the lights are seen beyond the 4°, and the efficiency of the lights in indicating the course is diminished, 2270, 2276, 2340, 2386–99; dark lane no practical danger, 2287; extent to which ships yaw, 2287–91; period of oscillation, 2414–8; lights seen from stemhead, 2345–8; no advantage whatever in large angle, 2474. Lights should be screened as finely as possible, 2271; especially in narrow waters, 2277; prefers some loss of uniformity of light to crossing, 2272–5, 2304–6; whatever old practice was, angle should now be made finer, 2313–7; his experience proves that fine screening is safe, 2449–56. Ships meeting nearly end on and screening, 2279–86, 2292–2312, 2317–36, 2339–40, 2419–43, 2459–73, 2475; porting across a ship's bows at half a mile, 2518–29. Lamps should be uniform, 2400–2, 2530; visibility of side lights, 2403–13; lenses and diffused light, 2477–91. Side-lights should have a fixed position abaft the masthead light, 2341–4, 2263–9, 2398, 2492–2502, 2511–17.

WICKS. Angle at which wicks should be placed, *Murray*, 99–100; *Samson*, 438–48; *Corry*, 1297–1301, 1336–40; the angle makes little difference to the power of the light and should not be fixed, *Harvie*, 3578–94, 3669–73, 3713–5, 3722, 3744. Position of wicks in the lantern, *Samson*, 447, 669–75; *Corry*, 1304–5; it varies greatly, *Richards*, 4239–41, 4242–3, 4319–23; *Laslett*, 4845–8, 4852–8. Width of wicks employed, *Corry*, 1302–3; *Scrutton*, 1354; *Richards*, 4285–7. Triplex wicks, *Corry*, 1306; *Chapman*, 4118–31, 4143–9, 4156–72; *Laslett*, 4704.

YAWING. Extent to which vessels yaw, *Colquitt*, 1526–9, 1535–47; *Posgate*, 1595–1601; *Hogg*, 1784–91, 1878–83; *Webster*, 2287–91, 2414–8; *Chandler*, 2793–4, 2838–42, 2846–8; *Hubback*, 3049–50; *Wade*, 3776–88, 3822–4, 3923–7. Yawing always recognised as such, *Chandler*, 2795–7; it is less liable to mislead if lights are finely screened, *ib.* 2846–8. Yawing and its relation to screening, *Anderson*, App. 6, No. 1; *Ruthven*, 2112–5. It is unreliable as an argument in favour of fine screening, *Murray*, 203, 5037–8, 5068–73; *Mensing*, 3197.
